5.6 The Developer shall construct a metered, buried, one-inch-diameter water pipe and wildlife drinking mechanisms in the portion of the conservation easement between lots 36 and 37. The drinking mechanisms and pipe material shall be constructed to the specifications of the SSMPA and the Conservancy and shall be completed within 3 months after the following three events have occurred: 1) finished grading on lots 36 and 37; 2) a water meter is available from the Las Virgenes Municipal Water District; 3) detailed construction drawings have been submitted to the Developer, or his successors. The wildlife drinker and adequate water shall be provided at the cost of the homeowners association, in perpetuity, and shall be reserved as an easement for access to the open space lot by the public entity holding title to it for the limited purpose of inspection or maintenance of the pipe and wildlife drinking area.

5.7 The water tank presently proposed to be placed on Lot 16 of Tract 33622 may be placed as shown on Exhibit "C" attached hereto, provided that the tank, pump, ancillary equipment, and fencing shall be screened consistent with the "Water Tank Access Road Revegetation and Screening Plan" attached hereto to prevent its being viewed from residential areas and the 118 Freeway.

5.8 No development on any lot may alter any natural stream bed, and such

stream beds shall be crossed only by a bridge reasonably designed to be compatible with the natural terrain.

5.9 No sound wall shall be erected on the south end of the property adjacent to the Simi Valley Freeway.

5.10 Any improvement on any lot shall be subject to architectural standards set forth in the CC&R's to insure the greatest practical compatibility between the improvements and the open space character of the area.

5.11 SSMPA shall be simultaneously provided two full sets of any grading plans that are submitted to either the Los Angeles County Departments of Regional Planning or Public Works.

5.12 There shall be no road access or other easements across Lots 25, 26, 30 or 31 to any adjacent parcel to the north or east.

6.0 Developer shall not remove any oak trees on the Project as part of the development except for some or all of the approximately 62 trees, identified in the current Oak Tree Report attached as Exhibit B, which are diseased or otherwise marginal. The number and location of such diseased trees which may be removed shall be provided to SSMPA and the Conservancy prior to any removal. Developer shall replace any removed trees on an two-to-one ratio. To the extent feasible, no colonies or clusters of endangered tar weed plants shall be removed.

7.0 Developer agrees to removal of all portions of existing mesh fence and poles (from one inch above existing ground level) that courses through the open space lot prior to map recordation.

8.0 Developer shall construct a metered, one-inch-diameter water pipe and wildlife

drinking mechanisms within either the unfenced portion of land described by Exhibit "C" or within immediately surrounding portions of the open space lot. The exact location of the drinking mechanism and pipe material shall be determined by the SSMPA and the Conservancy. Its distance from the water tank shall not exceed 150 feet. The drinking mechanisms shall be constructed to the specifications of the SSMPA and the Conservancy and shall be completed within 3 months after the following two events have occurred: 1) either a water meter or permanent water source from the tank is available from the Las Virgenes Municipal Water District, and 2) detailed construction drawings have been submitted to the Developer, or his successors. The wildlife drinker and adequate water shall be provided at the cost of the homeowners association, in perpetuity. Use of the water tank access road shall be reserved as an easement for access to the wildlife drinker by employees of the public entity holding title to it for the limited purpose of inspection or maintenance of the pipe and wildlife drinking area.

9.0 If the SSMPA or Conservancy determine that the Developer is in violation of the terms of this Agreement, or that a violation is threatened, the SSMPA or the Conservancy shall give at least thirty (30) days written notice to Developer of such violation and demand corrective action sufficient to cure or to prevent the violation and, where the violation involves injury to the Conservation Easements resulting from any use or activity inconsistent with the purpose of this Agreement, to restore the portion of the Conservation Easements so injured. If Developer fails to cure the violation within thirty (30) days after receipt of notice from SSMPA or Conservancy, or under circumstances where the violation cannot reasonably be cured within a thirty (30) day period, fail to begin curing such violation within the thirty (30) day period, or fail to continue diligently to cure such violation until finally cured, SSMPA or Conservancy may

bring an action at law or in equity in a court of competent jurisdiction to enforce the terms of this Agreement, to enjoin the violation by temporary or permanent mandatory or prohibitory injunction (including, without limitation, preliminary *ex parte* relief; but, if application is made *ex parte*, then with at least 72 (seventy two) hours advance written notice given by fax during normal business hours to Developer, to recover any damages to which it may be entitled for violation of the terms of this Agreement or for injury to any ecological values protected by this Agreement and to require the restoration of the Conservation Easements to the condition that existed prior to any such injury. Without limiting Developer's liability therefore, SSMPA or Conservancy, in its sole discretion, may apply any damages recovered to the cost of undertaking any corrective action on the Conservation Easements consistent with the provisions of this Agreement. If the SSMPA or Conservancy, in its reasonable judgment based on a preponderance of evidence, determines that seriously deteriorating, or about to deteriorate, circumstances of substantial impact to the ecology of the Conservation Easements require remedial or preventive action within less than thirty (30) days to prevent or to mitigate significant damage to the ecological values of the Conservation Easements and it reasonably appears to the SSMPA or Conservancy based on a preponderance of evidence that Developer is unwilling, unable or unmotivated to take such faster action (or to stop its own actions; if such actions are the cause of the harm), then, and only then, the SSMPA or Conservancy may pursue its legal and equitable remedies under this Section with only ten (10) days prior written notice to Developer rather than the normal thirty (30) days notice. The SSMPA or Conservancy's rights and remedies under this Section apply equally in the event of both actual and threatened violation of the terms, covenants, conditions and provisions of this Agreement, and Developer agrees that the SSMPA or

Conservancy's remedies at law for any violation of the terms, covenants, conditions and provisions of this Agreement are inadequate and that the SSMPA or Conservancy shall be entitled to the injunctive relief described in this Section, both prohibitive and mandatory, in addition to such other relief to which the SSMPA or Conservancy may be entitled, including specific performance of the terms, conditions, covenants and provisions of this Agreement, without the necessity of proving either actual damages or the inadequacy of otherwise available legal remedies. The SSMPA or Conservancy's rights and remedies described in this Section shall be cumulative and shall be in addition to all rights and remedies now or hereafter existing at law or in equity.

9.1 The prevailing party in any action or proceeding brought by either party to enforce the provisions of this Agreement shall be entitled to reimbursement of its costs and expenses (including, without limitation, experts' fees) and reasonable attorneys' fees from the other party.

9.2 The exercise of any right or remedy by either party hereunder is at the sole discretion of said party and the failure to exercise or delay in the exercise of any right or remedy shall not impair the right or remedy nor act as a future waiver of said right or remedy with respect to the claimed breach, with respect to subsequent identical breaches or with respect to any other breaches, and the only limitation on the exercise of said right or remedy shall be the applicable statutory limitations period, defenses of laches being specifically waived, or the agreed upon limitations period set forth in the next sentence. If no set period of time is set forth in any statute for limiting the exercise of any legal or equitable remedy, then the parties agree that no such remedy, whether legal or equitable, shall be exercisable more than five (5) years after the

party claiming such right or remedy actually did or could have, by means of ordinary diligence, discovered the breach giving rise to such right or remedy.

9.3 Nothing contained in this Agreement shall be construed to entitle the SSMPA or Conservancy to bring an action against Developer for any injury to or change in the Conservation Easements resulting from causes beyond Developer's reasonable control (even when Developer is ordinarily but not grossly negligent) including, without limitation, fire, flood, storm and earth movement, or resulting from any action (even when Developer is ordinarily but not grossly negligent) taken by Developer under the provisions of this Agreement to preserve health or safety or to restore or to prevent injury to the Conservation Easements.

9.4 Except as otherwise provided in this Agreement with respect to indemnification for certain matters, Developer retains all responsibilities and shall bear all costs and liabilities of any kind related to the ownership of the Conservation Easements including, without limitation, maintenance of reasonable amounts of comprehensive general liability insurance coverage. Developer and the SSMPA and Conservancy shall each keep the Conservation Easements free of any mechanics and/or material persons' liens with respect to work performed on or materials supplied to the Conservation Easements by or on their respective behalfs.

9.5 Developer shall be solely responsible for all property taxes assessed against the Conservation Easements.

10.0 The parties hereto agree that it may be in their best interests to amend this Agreement from time to time in order to comply with changed governmental regulations, or to adapt the provisions of this Agreement to changed physical conditions, or for any other purpose

which the Parties hereto agree would facilitate the intent and provisions of this Agreement.

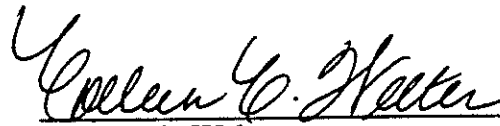

11.0 The Exhibits attached hereto, and made a part hereof by reference, are as follows:

11.1 Exhibit "A": Vesting Tentative Tract Map No. 44327, dated 8/24/93, as initialed on 10/6/93 by Robert McMurry and Carlyle Hall.

11.2 Exhibit "B": Oak Tree Report No. T-44327, dated 1/15/92, by Poly Associates.

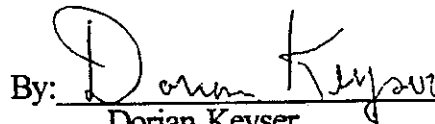

11.3 Exhibit "C": Map dated 8/1/97, titled "Proposed Water Tank Site and Access Road For Vesting Tentative Tract No. 44327."

In witness whereof the parties hereto have executed this Agreement the day and year in first above-written.

MEMORANDUM OF AGREEMENT RE ACQUISITION OF REAL PROPERTY

THIS MEMORANDUM OF AGREEMENT RE ACQUISITION OF REAL PROPERTY "Memorandum of Agreement") is made and entered into as of the 29th day of December, 1997, by and among between THE SANTA MONICA MOUNTAINS CONSERVANCY ("Conservancy"), the Conservancy's Designee, MOUNTAIN RECREATION CONSERVATION AUTHORITY ("Designee") CHATSWORTH RIDGE ESTATES, LLC, a California limited liability company. ("CRE") and CHATSWORTH RIDGE ESTATES, INC. a California Corporation (CRE Corp.)

Conservancy, Designee, and CRE have entered into that certain "Agreement Re Acquisition of Real Property", dated December 29, 1997, which related to real property, in the County of Los Angeles, State of California, legally described on Exhibit "A"; Exhibit B; Exhibit B-1, Exhibit C; Exhibit C-1, Exhibit D, Exhibit D-1 and Exhibit G. At such time as this Memorandum of Agreement no longer effects a particular parcel of property attached hereto as an exhibit, then the parties hereto agree to release such parcel of property from the terms of such Agreement in a form suitable for recording.

IN WITNESS WHEREOF, the parties have executed this Memorandum of Agreement as of the date above.

EXECUTIVE SUMMARY

Imbsen & Associates, Inc. (Imbsen) was retained by B& E Engineers to perform Advance Planning Studies on two structures within the Chatsworth/Deer Ridge Project, funded by the Presidio Group, and located in the greater Los Angeles County. Imbsen submitted a Draft Report on March 24, 2000 and a revised Draft Report on April 13, 2000 in which cast-in-place, precast, and steel superstructures were considered for both the Devil Canyon Creek bridge at "A" Street (3-span bridge) and the Devil Canyon Creek Bridge at "other" Street (single span bridge). The Draft Reports also highlighted the associated construction costs and sequences for both bridges.

A meeting was held at B& E Engineers on April 13, 2000 to discuss alternatives and special considerations, including the Santa Monica Mountains Conservancy Property in the vicinity of the structures. Present at this meeting were Eli Aramouni, Imbsen, Richard Garlinghouse, Presidio Group, and Hans Girard and Ramy Awad from B& E Engineers. Attendees discussed the different bridge alternatives, construction sequences and access, costs and schedule.

The following alternatives were considered for the study:

"A" Street Bridge (3-Span Bridge) Alternatives

			Construction Cost (including 10% Mobilization & 0% Contingency)
Current Alignment as presented by B&E Engineers	Bridge Length = 397'0" Bridge Width = 47'9"	Cast-in-Place Superstructure	\$1,972,000*
		Precast Prestressed Superstructure	\$2,116,000*
		Steel Superstructure	\$3,308,000
	Bridge Length = 397'0" Bridge Width = 64'0"	Cast-in-Place Superstructure	\$2,334,000
		Precast Prestressed Superstructure	\$2,505,000
		Steel Superstructure	
	Bridge Length = 295'0" Bridge Width = 64'0"	Cast-in-Place Superstructure	\$2,543,000

RECOMMENDATION

Cast-in-place, post-tensioned, box girder superstructures in California are the most economical types of bridges built in the State. About 80 percent of all bridges built in the State of California are box girders because of ease of construction by contractors, cost to construct, appearance, high torsional resistance and adaptability to curved alignments. Box girders also conceal and protect utilities, pipes and conduits. However, extensive falsework and formwork are required to build box girder bridges, making them undesirable when crossing a water body, viaduct, or an environmentally sensitive habitat.

The Santa Monica Mountains Conservancy Property (SMMC), located in the vicinity of the structures, is an environmentally sensitive habitat. Precast Prestressed Concrete Girders are an excellent choice of construction to span over the SMMC property lines, thus reducing or eliminating the construction impact on the site. Precast fabrication plants are located in Long Beach, Perris, Lathrop, and Rialto, California. However, Precast Girders generally cost more than cast-in-place reinforced or prestressed box girders and require careful handling after fabrication.

Imbsen recommends the Precast Prestressed Girders alternative if the goal is to reduce the construction impact on the SMMC, and the Cast-in-Place Prestressed Box Girder alternative if access is provided on the SMMC property.

1. DEVIL CANYON CREEK BRIDGE AT "A" STREET

1.1 Proposed Structure

A three-span structure will be the most economical configuration given the provided site conditions and geometry of this location. An Advance Planning Study (APS) sheet has been prepared for the more feasible bridge length and to compare cost estimates between two different structure types. Option A uses precast prestressed concrete bulb-tee girders and Option B uses a cast-in-place prestressed concrete box girder. Other alternatives previously investigated were a shorter length bridge with taller abutments and longer and higher retaining walls. In addition, an alternative alignment was also explored to shorten the main span length, but at the expense of three residential lots. A third structure type consisting of steel plate girders was also considered and the estimated cost was much higher than the precast and cast-in-place options.

The proposed bridge width consists of a 40' travel way (20' for each direction). A Concrete Barrier Type 26 has been assumed on the south side to provide a 5' raised sidewalk and a 1' wide concrete barrier with a pedestrian handrail on top. In addition, a Concrete Barrier Type 25 with a Tubular Handrailing Type 25 has been assumed on the north side to meet bicycle requirements.

1.1.1 Construction Sequence

Construction sequence for cast-in-place concrete box girder bridges is well understood and practiced by bridge contractors in California. Erection of precast girders is also a common bridge construction practice, but not as frequent as the cast-in-place technique in California.

The first order of work for the bridge construction is to provide an access ramp down to the bent locations. It is assumed these ramps will begin near the abutment locations and provide access for the drill rig, erection crane, concrete pump truck, and concrete trucks. Large cranes may require as many as seven trucks legally loaded for over-the-road service for delivery to the project site. Typically, the larger the crane is the less "agile" it may be on sloping or unstable ground.

Substructure (abutment) construction usually involves backhoes or hydraulic excavators to make excavations for the spread footings and involves:

- Excavate for the placement of footings

- Form footing
- Place footing and some abutment wall reinforcing steel
- Place footing concrete
- Form abutment stem wall
- Place remaining stem reinforcing steel and close up forms
- Place stem concrete up to bearing seat

Construction of cast-in-drilled-hole (CIDH) concrete piling (in dry stable ground) usually involves crane-mounted drilling equipment and a service crane to handle the rebar cage. The process usually is:

- Drill hole and prepare reinforcing bar "cage" to be inserted into the drilled hole
- Place reinforcing cage (usually extending to top of future column)
- Place concrete to pile cut-off elevation
- Form column (extension of the pile above ground)
- Place concrete to 1" above; the future structure soffit or the drop cap soffit

Construction of the drop bent cap for Option A (PC/PS Bulb-Tee girder) usually involves a crane and falsework to provide a form to cast the cap as follows:

- Erect falsework between and around both columns to provide a working platform
- Erect forms for cap on platform
- Place reinforcing steel in cap and reinforcing steel to be used later in the bent diaphragm
- Place bent cap concrete
- Remove falsework after concrete strength has been reached

Superstructure construction for precast girders (**Option A**) can begin as soon as the concrete strength has been reached at both the abutment stems and the drop bent cap, maximum 28-days after placing. Precast prestressed concrete bulb-tee girders (that were cast in the manufacturers yards months before) are brought to the job site and laid down on the approach fill to each abutment. The lengths of these girders will likely be 60' to 90' and the process will be:

- Post-tension the girders together at the job site to arrive at the final span lengths, usually done in the approach roadway.
- Erect the end span girders (span 1 and span 3) by using two cranes one up on the approach road and the other likely to be down on the access ramp provided for the bent construction

- Erect the main span girders (span 2) by using two cranes placed on the approach road or by using high lines also placed (supported) in the approach road.
- Erect forms for bent cap diaphragms, abutment diaphragms and intermediate diaphragms
- Place reinforcing steel in diaphragms
- Place concrete in diaphragms (may be done later with "deck pour")
- Erect form for deck or use precast deck panels
- Place reinforcing steel for the deck
- Place "deck pour" concrete
- When the concrete meets the design strength, the bulb-tee girders are post-tensioned together using prestressing strands for the entire length of bridge (performed from abutments)
- The bridge is finished by filling prestressing blockouts and placing the abutment backwalls while forms, reinforcing, and concrete are placed for the concrete barriers
- The backfill is placed and compacted behind the abutments, final cleanup is done, and the structure is ready to open to traffic.

Superstructure (falsework) construction, for cast-in-place concrete (**Option B**), is often started simultaneously with the substructure construction since it takes more time for most sites. When both are complete the following progression occurs:

- Place reinforcing steel for the soffit slab and girder stems (post-tensioning ducts are also placed in the girder stems)
- Erect girder stem forms
- Place concrete in soffit and stem pour (a little over half of the superstructure concrete is placed)
- Place utilities (or casings for the utilities) to be carried inside the box girder superstructure and then the girder stem forms are stripped and flipped to be used as "lost-deck" forms for the bottom of the deck slab
- Place reinforcing steel for the rest of the superstructure
- Place "deck pour" concrete
- When the concrete meets the design strength, the box girder is post-tensioned with prestressing strands from the abutments
- The bridge is finished by filling prestressing blockouts and placing the abutment backwalls while forms, reinforcing, and concrete are placed for the concrete barriers
- The backfill is placed and compacted behind the abutments, final cleanup is done, and the structure is ready to open to traffic.

1.1.2 Types of Foundations

The presence of groundwater will be a major consideration in design and construction of the large diameter CIDH piling at the bents and in turn will affect the cost. When groundwater is anticipated, the CIDH piling will be designed to accommodate construction inspection pipes. Additionally, if soft cohesive soils or loose sands are expected then a temporary or permanent steel casing will be used during construction. Conversely, if a rock or hard material stratum is encountered where conventional CIDH methods are not feasible then pier columns are used. The term pier column is used to describe the construction method where a large diameter pile is cored vs. drilled into the hard material. The cost of this construction technique is usually higher than for drilling, but the length of pile is usually reduced so the net effect is minor.

At the abutments spread footing type foundations have been assumed for cost estimating; however, if the existing ground is not capable of supporting the loads from the proposed high-cantilevered abutments other alternatives are available. Driven piles can be used to transfer load through a weak soil stratum into a stronger stratum by either end bearing at the pile tip or through side friction into the surrounding soil, or a combination of both. Typically, precast concrete piles or steel piles are used. Often times a precast concrete pile is specified, while the Special Provisions may provide for the substitution of steel piles. For locations where boulders may be present in the stratum steel piles would be chosen and concrete piles precluded. In addition, where soil stratum contains corrosive properties concrete piles using special cement are selected and steel piles are normally not acceptable.

Another option is to use drilled piles. If noise is a concern at a construction site, usually in an urban setting, then construction of drilled piles is preferred over driven piles. When groundwater is anticipated, 24" or greater diameter CIDH piles must be specified. Furthermore, if boulders are expected then the size of the boulders will have a direct effect in specifying the size of the CIDH piles. Soft soil conditions also require special construction techniques just as they do for large diameter CIDH piles described above.

1.1.3 Superstructure

The two proposed types are presented in the following table.

Option	Structure Type	Bridge Length	Span Lengths	Superstructure Depth
A	PC/PS Conc Bulb-Tee Girder	397'-0"	130'-185'-82'	8'-6"
B	CIP/PS Conc Box Girder	397'-0"	130'-185'-82'	7'-6"

1.1.4 Substructure

All abutments and retaining walls have been assumed to be on spread footing foundations. High-cantilevered seat type abutments have been assumed for both options. The bents have been assumed to consist of circular columns (two-column bents) on large 72" diameter cast-in-drilled-hole (CIDH) piles. The only difference between the two options is a drop cap (reinforced concrete beam) will be used at the bents for Option A (PC/PS Bulb-Tee Girders).

1.1.5 Construction Cost Estimate

Alternatives and estimates are based upon the following assumptions:

- Construction processes and completed structures must meet Los Angeles County requirements.
- Access for "normal" construction equipment is available from both ends at each site (rough grading will be done to "A" Street site).
- In-situ Geotechnical materials are adequate for the loads imposed (*Geotechnical Report* will make site-specific foundation recommendations). Estimated costs for cast-in-drilled-hole concrete piling and spread footings are based on stable, dry ground conditions (i.e., no casings, slurry, or other special measures will be required for substructure design or construction).
- Environmentally sensitive area(s), if any, will not change span length or bent spacing shown or dictate falsework design.

The two construction cost estimates are presented below, which includes 10% for mobilization and no contingencies. Contingencies will be included with the overall infrastructure project estimate.

Option	Structure Type	Bridge Length	Retaining Walls Total Length	Cost Estimate*
A	PC/PS Conc Bulb-Tee Girder	397'-0"	106'	\$2,116,000
B	CIP/PS Conc Box Girder	397'-0"	106'	\$1,972,000

*No contingencies included

2. DEVIL CANYON CREEK BRIDGE AT "OTHER" STREET

2.1.1 Proposed Structure

A simple span structure will be the most economical configuration given the provided site conditions and geometry of this location. Advance Planning Study (APS) sheets have been prepared for two different bridge lengths to compare cost estimates and their relation between providing a longer bridge and shorter and lower retaining walls vs. a shorter bridge with taller abutments and longer and higher retaining walls.

The proposed bridge width consists of a 36' travel way (18' for each direction). A Concrete Barrier Type 26 has been assumed on the east side to provide a 5' raised sidewalk and a 1' wide concrete barrier with a pedestrian handrail on top. In addition, a Concrete Barrier Type 25 with a Tubular Handrailing Type 25 has been assumed on the north side to meet bicycle requirements.

2.1.2 Construction Sequence

See Bridge at "A" Street description. The main difference is that no CIDH piling (bent construction) will be required for the simple span bridge at "Other" Street.

2.1.3 Superstructure

The two alternatives investigated are presented in the following table.

Alternative	Option	Structure Type	Bridge Length	Superstructure Depth
1	A	PC/PS Conc Bulb-Tee Girder	111'-0"	6'-6"
1	B	CIP Reinforced Conc Box Girder	111'-0"	6'-6"
2		CIP/PS Conc Box Girder	168'-0"	7'-9"

2.1.4 Substructure

All abutments and retaining walls have been assumed to be on spread footing foundations. High-cantilevered seat type abutments have been assumed for all alternatives. The table below summarizes the differences between the alternatives.

Alternative	Bridge Length	Abutment Heights	Retaining Wall Heights	Retaining Wall Total Length
1	111'-0"	28'-36'	12'-36'	200'
2	168'-0"	18'-20'	10'-20'	85'

2.1.5 Construction Cost Estimate

Alternatives and estimates are based upon the following assumptions:

- Construction processes and completed structures must meet Los Angeles County requirements.
- Access for "normal" construction equipment is available from both ends at each site.
- In-situ Geotechnical materials are adequate for the loads imposed (*Geotechnical Report* will make site-specific foundation recommendations). Estimated costs for spread footings are based on stable, dry ground conditions.
- Environmentally sensitive area(s) if any, will not change span length shown or dictate falsework design.

The construction cost estimates are presented below, which includes 10% for mobilization and no contingencies. Contingencies will be included with the overall infrastructure project estimate.

Alternative	Option	Structure Type	Bridge Length	Retaining Wall Total Length	Cost Estimate*
1	A	PC/PS Conc Bulb-Tee Girder	111'-0"	200'	\$990,000
1	B	CIP Reinforced Conc Box Girder	111'-0"	200'	\$971,000
2		CIP/PS Conc Box Girder	168'-0"	85'	\$756,000

* No contingencies included

CONSTRUCTION COST - \$

\$2,116,000 *

* Includes 10% mobilization only; no contingencies included

TYPES CONSIDERED:

1. 397' long 3-span structure with 106' of retaining walls.
2. 295' long 3-span structure with 327' of retaining walls.
3. 380' long 3-span structure with 106' of retaining walls on a different alignment.

For most alternatives, three structure types were considered.

- A. Precast prestressed concrete bulb-tee girder
- B. Cast-in-place prestressed concrete box girder
- C. Steel plate girder

PREVIOUS COMMUNITY AESTHETIC OR ECOLOGICAL COMMITMENTS:

Presently unaware of any previous community aesthetic commitments.
 The Santa Monica Mountains Conservancy Property Line is an ecological concern.

ARCHITECTURAL RECOMMENDATIONS:

No architectural recommendations were provided.
 The Advance Planning Study sheet shows vertical exterior girders for the cast-in-place option.
 Alternative 1 (preferred) uses round columns and CIDH piles of 72" diameter for all structure types.
 High-cantilevered concrete abutments on spread footings were assumed for all alternatives.
 Concrete Barrier Type 26 was provided on the south side of the bridge for pedestrian access.
 Concrete Barrier Type 25 was provided on the north side of the bridge.

ENGINEERING AND ARCHITECTURAL SUMMARY:

The precast prestressed concrete bulb-tee girder was selected because the construction methods are better suited to the concerns over the Santa Monica Mountains Conservancy Property Line.

APPENDIX E

FUEL MODIFICATION PLAN

LEGEND

ZONE A - 20' WET ZONE:
 This zone extends 20' from the edge of any combustible structure and may include pad or graded slope.
General Requirements:
 Maximum of 20' beyond the edge of combustible structures, attached accessory structures, or appendages and projections. Except for dwarf varieties or mature trees small in stature, trees are generally not recommended within Zone A (for reasons which go beyond fire issues such as possible maintenance and safety liabilities) and are therefore not included in the planting guide (as provided by the County of Los Angeles Fire Department). For purposes of the fuel modification plan, all combustible accessory structures, appendages, or projections within 20' of the combustible structure will be considered as attached.
 Vegetation on the pads is limited to Los Angeles County approved ground covers, green lawns, and an approved variety of ornamental plants.
 Vegetation on the slopes is limited to native shrubbery and approved ornamental plant species.
 All graded slopes, planting and irrigation are to conform to the grading ordinances.

Special Requirements:
 The areas are to be irrigated. The manufacturer slopes are to be planted and irrigated in accordance to County of Los Angeles grading ordinances. Irrigation by automatic or manual sprinkler systems to maintain healthy vegetation with high moisture content. Irrigation shall be designed to establish and maintain planted natives and ornamentals. Irrigate away from native oak trees and outside the drip-line.
 Regular pruning of foliage and removal of plant litter and dead wood to reduce fuel load and vertical continuity once the vegetation is established.
 Target trees are not allowed within 10' of the combustible structures. Other tree species may be allowed pursuant to the Fire Code but it is not recommended.
 Special consideration will be given to rare or endangered species, geological hazards, tree ordinances, or other conflicting restrictions.

Maintenance - Annual Basis:
 Required continual removal and/or thinning of undesirable combustible vegetation, replacement of dead/dying fire resistant plantings. Regular trimming to prevent ladder fuels.
 Maintenance of the operational integrity and programming of the irrigation system.

ZONE B - IRRIGATED ZONE:

General Requirements:
 Irrigation of plant materials located on remanufactured slopes, with manual or automatic irrigation systems, to maintain healthy vegetation with high moisture content.

Zone B extends from the edge of Zone A, (located a minimum of 20' from any combustible structure), and consists of a variable length not to exceed 180'. The combined distances of Zone A (as listed in this text as 20' from any combustible structure) and Zone B (as listed in this text as 180' outside of Zone A) add up to a total of 200' from any structure. Within Zone B, native or existing vegetation shall be removed. Individual plantings are to be thinned to reduce the fuel load.
 Any County approved single specimen of tree, shrub or groundcover is permissible provided that they do not form a means of rapidly transmitted fire from the native growth to any structure. (See 'Fuel Modification Plan Guidelines' publication available from the County of Los Angeles Fire Department for a complete list of plant materials and further information.)

Special Requirements:
 Special consideration will be given for rare or endangered species, geologic hazards, tree ordinances, or other conflicting restrictions as identified in the environmental documentation.

Maintenance - Annual Basis:
 Requires continual removal and/or thinning of undesirable combustible vegetation, replacement of dead/dying fire resistant plantings.
 Maintenance of the operational integrity and programming of the irrigation system.

ZONE C - THINNING ZONE:

Extends from outermost edge of Zone B to 200' or property line.
 Predominantly existing vegetation with removal of the majority of undesirable plant species including chamise, red shank, California sage brush, common buckwheat and sage (Appendix I).
 Reduce fuel loading by reducing the fuel in each remaining shrub or tree without substantial decreased in the canopy cover or removal of soil holding root systems.
 Some replacement planting with ornamental or less flammable native species to meet minimum slope coverage requirements of the city or county public works, landscape or hillside ordinances.
 Natural vegetation is thinned by reduced amounts as the zone moves away from the development.
 Removal of all dead vegetation, all fine fuels reduced to 3 inches in height.
 Any plans selected for planting in this zone will be chosen from the approved plant list for the setback, irrigated, or thinning zone and given geographical areas (see Appendix II).

Access Road:
 Clear and remove flammable growth for a minimum of 10 feet on each side of access road. (F.C. 1117.10).
 Fire access roads, driveways and turnarounds shall be maintained in accordance with the Fire Code. Fire access road shall have unobstructed vertical clearance to the sky. (F.C. 902.2.2.1)
 Within the 10 foot clearance zone it is recommended that proposed surface fuels be appropriately spaced and maintained at a height not to exceed 18 inches. Proposed trees should be planted outside the 10 foot clearance zone.

Oak Trees:
 Contact Deputy Forester Keith Deagon of the County of Los Angeles Fire Department Forestry Division at (818) 890-5719 for any oak issues or for any issues related to oaks within the project.

Maintenance
 Requires annual removal and/or thinning of undesirable combustible vegetation, replacement of dead/dying fire resistant plantings, maintenance of the operational integrity and programming of the irrigation system.
 Pruning of foliage to reduce fuel load, vertical continuity, and removal of plant litter and dead wood.
 Regular trimming to prevent ladder fuels. Prune lower branches of trees and tree-form shrubs up to 1/3 of their height (up to a maximum of 6' above the ground).
 Debris and trimmings produced by thinning and pruning shall be removed from the site or chipped and evenly dispersed in the same area to a maximum depth of 5 inches.
 Recommended minimum spacing is 20-30 feet between canopies for trees and 15 feet or three times the diameter of the individual crowns for large shrubs.
 Ground covers shall be maintained at a height not to exceed 5 inches.
 All grasses shall be maintained at a height not to exceed 3 inches.
 Compliance with the Fire Code is a year round responsibility. Enforcement will occur following inspection by the Fire Department annually or as needed. Annual inspections are generally conducted following natural drying of fine fuels. This occurs between the months of April and June. All future plantings shall be in accordance with the County of Los Angeles Fire Department Fuel Modification Guidelines.

Long Term Maintenance Agreement

The homeowner(s) agree to be responsible for the long-term maintenance of this fuel modification plan, as described herein.

Homeowner	Date
Homeowner	Date

Los Angeles, CA 90017**

Date:

November 12, 2001

SETTING

Climate and Meteorology

Regional Climate

A semi-permanent high-pressure cell is the dominant climatic influence over the eastern North Pacific Ocean, particularly during the summer. The high-pressure cell produces a predominantly northwesterly flow of maritime air over the California coastal waters. During winter, the Pacific High weakens and moves south, resulting in weaker and less persistent northwesterly winds along the California coast. The weakened Pacific high pressure ridge allows for the periodic intrusion of fronts and storms into California in winter. Such storm activity is, however, much less intense in Southern California than in more northerly latitudes.

As the air mass approaches the coast of California, this large scale circulation pattern is modified by local influences. The differential heating between the desert and the adjacent Pacific Ocean modifies the prevailing winds, enhancing them during the warmer half of the year and weakening them during the colder portion. On a local and sub-regional basis, the air flow in California is channeled by its mountain ranges and valley. The coastal mountain ranges limit the flow of maritime air into the interior of California. This transition from a cool and damp marine environment to a dry and warm continental climate therefore occurs over a fairly short distance.

South Coast Air Basin

The South Coast Air Basin (SCAB) is a 6,600 square mile coastal plain bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. The SCAB includes all of Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties. Basinwide conditions are characterized by warm summers, mild winters, infrequent rainfall, moderate onshore daytime breezes, and moderate humidities.

All seasons generally exhibit onshore flows during the day and offshore flows at night, after the land cools below the temperature of the ocean. The likelihood of strong offshore flows, including Santa Ana winds, is greater during winter than during summer [California Air Resources Board (CARB) 1984].

The topography and climate of Southern California combine to produce generally poor air quality in the Air Basin. The combination of low temperature inversion; meteorological conditions such as light winds, shallow vertical mixing, and extensive sunlight; and topographical features such as adjacent mountain ranges hinder dispersion of air pollutants, thus contributing to poor air quality, especially in inland valleys of the basin.

Existing Air Quality

Air Pollutant Emissions

o **Criteria Air Pollutants**

The most current air pollutant emissions estimate for the SCAB was recently prepared by the California Air Resources Board (2001). In 2000, about 7,200 tons per day (TPD) of carbon monoxide (CO); 1,090 TPD of volatile organic compounds (VOC); 1,210 TPD of nitrogen oxides (NO_x); 80 TPD of sulfur oxides (SO_x); and 360 TPD of respirable particulates (PM-10) were emitted in SCAB (California Air Resources Board; 2001 California Almanac of Emissions and Air Quality). About 81% of the CO, about 63% of the NO_x, 31% of the SO_x, and about 52% of the VOC were emitted by on-road vehicular sources. Past studies have shown relatively little seasonal variation in air pollutant emissions. Seasonal variations in meteorology, however, result in marked seasonal differences in atmospheric concentrations of pollutants (SCAQMD and SCAG 1991).

o **Toxic Air Contaminants**

Substantial concentrations of toxic air contaminants (TAC), both carcinogenic and non-carcinogenic, exist in urban areas as a result of emissions from mobile sources such as motor vehicles and aircraft, and stationary sources such as gasoline service stations automotive repair shops, dry cleaners, various types of manufacturing, and large industrial operations. According to CARB (2001), the lifetime individual cancer risk from toxic air pollution in the SCAB is 275 in a million (due mainly to benzene, 1,3-butadiene and formaldehyde). In the United States, the lifetime cancer risk from all sources is around 275,000 in a million. Toxic air pollution constitutes 0.1 percent of cancer risk due to all risk factors. Diesel particulate matter (DPM) is currently estimated to pose a lifetime cancer risk of 720 in a million, but a number of statewide DPM-control regulations have been adopted that will sharply reduce DPM exposure risk within the next few years.

Ambient Air Pollution Concentrations

◦ South Coast Air Quality Management District Monitoring

SCAQMD operates a regional air quality monitoring network that provides information on average concentrations of those air pollutants for which State or federal agencies have established ambient air quality standards. Table 1 is a six year summary of monitoring data for the major air pollutants, collected at the SCAQMD's Reseda monitoring station. This station is the nearest SCAQMD monitoring station to the project site and, among SCAQMD's current stations, is the one most representative of air quality conditions in the project area. Because there are no measurements of respirable particulate matter (PM-10) made in the western San Fernando Valley, Table 1 also includes PM-10 data from the nearest Ventura County APCD monitoring station in Thousand Oaks.

Over the last 15 years, air quality in the SCAB has improved substantially. Violations of the State and national standards for lead have been completely eliminated. The State and national SO_x standards were met throughout the period. Second-stage smog alerts have disappeared and the number of first-stage alerts has dropped dramatically. The federal annual standard for NO₂ is now met almost every year as is the one-hour CO standard. The likelihood of meeting the federal 8-hour CO standard is a realistic expectation in the not-too-distant future. No significant trend, however, can be seen over the last decade for which respirable particulates (PM-10) have been monitored.

◦ Criteria Air Pollutants

Ozone

Ozone (O₃) is not emitted directly by any major stationary or mobile air pollutant sources in SCAB. It is a "secondary" air pollutant formed in the atmosphere through a complex series of photochemical reactions involving hydrocarbons and NO_x, primarily nitrogen dioxide. Substantial O₃ formation generally requires a stable atmosphere with strong sunlight.

O₃ is considered a pollutant of regional rather than local concern. Significant progress has been made over the past decade in reducing O₃ concentrations in the SCAB, but O₃ concentrations in the SCAB still exceed the national standards far more frequently than in any other area of the U.S. O₃ levels near Chatsworth exceeded the State standard on less than 25 days per year with less than 5 annual violations of the less stringent federal standard. The one-hour federal ozone standard was not exceeded at all in 1997 in the

western San Fernando Valley for the first time ever in the Reseda SCAQMD station monitoring history. This standard was also met again in 1999 and again in 2000. Although there is a noticeable improvement trend in O₃ levels from 1995-2000, one first-stage smog alert (one hour \geq 0.20 ppm) in the 6-year period was recorded in 1996.

Carbon Monoxide

Carbon monoxide (CO) is a product of incomplete combustion emitted, along with carbon dioxide, by motor vehicles, power plants, refineries, industrial boilers, ships, aircraft, and trains. In urban areas, CO is emitted primarily by motor vehicles. CO concentrations are influenced by local meteorological conditions, primarily wind speed, topography, and atmospheric stability. Excesses of the State CO standard in the SCAB tend to occur near major motor vehicle traffic corridors when meteorological conditions allow CO to accumulate. CO standards are infrequently exceeded near the project site. The eight-hour state and federal CO standard has averaged slightly less than one violation per year since 1995. The one-hour State CO standard has been met with a wide margin of safety throughout the last decade.

Nitrogen Dioxide

Nitrogen dioxide (NO₂) is a product of high temperature combustion, emitted generally by the same sources as CO. High concentrations of NO₂ cause the brown haze readily observed in urban areas during periods of heavy air pollution. Los Angeles is the last county in the U.S. to meet the national annual NO₂ standard; the standard has been met since 1992 with a very slim margin. State one-hour NO₂ standards are met near the project site by a substantial margin.

Respirable Particulate Matter

Respirable particulate matter (PM-10) consists of suspended particles 10 microns in diameter or less. Particulates in the atmosphere result from natural sources, such as wind erosion and ocean spray, and from human activities. Man-made sources include many types of dust- and fume-producing industrial and agricultural operations; fuel combustion and vehicle travel; grading, excavating, demolition, and blasting for construction; and atmospheric chemical and photochemical reactions. Motor vehicle traffic is the major source of PM-10 from dust lofted by vehicular turbulence.

State PM-10 standards are exceeded at the nearest air monitoring station on an average of eight percent of all measured days. The

three times less stringent federal PM-10 standard has never been violated at the nearest PM-10 monitoring location.

Monitoring data are only beginning to become available on compliance with the recently adopted (1997) federal standard for ultra-small diameter (2.5 microns or less) particulate matter called "PM-2.5." PM-2.5 monitoring began near mid-year at Reseda in 1999. One violation of the federal PM-2.5 standard of $65 \mu\text{g}/\text{m}^3$ for 24 hours was recorded in 71 samples in 1999, and two violations in 108 measurement days were observed in 2000.

Air Quality Planning and Regulatory Environment

Regulatory Agencies

o Federal Agencies

Regulatory control over air quality relative to meeting federal clean air standards rests with the U.S. Environmental Protection Agency (EPA). EPA derives its authority from the federal Clean Air Act.

The original federal Clean Air Act (CAA), enacted in 1970, was extensively revised in 1977. The 1977 CAA Amendments revised National Ambient Air Quality Standards (NAAQS) designed to protect public health and welfare. Standards were established for criteria air pollutants, O_3 , CO, NO_2 , SO_2 , and total suspended particulates (TSP). In later years, the TSP standard was revised to address PM-10, and a lead standard was established. A PM-2.5 standard was added in 1997.

The 1977 CAA Amendments (CAAA) required each state to prepare a State Implementation Plan (SIP) describing its plans for attaining compliance with federal air quality goals. The 1977 CAAA also classified air basins as either "attainment" or "non-attainment" areas for each criteria air pollutant, based on whether or not the established standards have been achieved. The 1990 CAAs reflect revised requirements and deadlines for attainment of NAAQS.

o State Agencies

The California Air Resources Board (ARB) is responsible for state air quality programs. The ARB may delegate a portion of its responsibilities to local or sub-regional jurisdictions. The ARB generally retains authority over statewide programs such as motor vehicle emission standards while air quality monitoring, stationary source permitting and enforcement, or basinwide air quality planning are subordinated to local air pollution control districts (APCD) or air quality management districts (AQMD).

State ambient air quality standards (SAAQS) predate the establishment of federal AAQS by several years. These standards are designed to protect those people most sensitive to adverse air pollution exposure (called "sensitive receptors"). Existing state and federal AAQS are shown in Table 2. The CAAA of 1990 required that EPA consider revising standards if health information warrants. Revisions to the national ozone standard and establishing a standard for PM-2.5 resulted from this review process. SAAQS are generally equal or normally more stringent than national AAQS.

Local Agencies

o South Coast Air Quality Management District

SCAQMD is the regional agency charged with meeting state and federal air quality goals. SCAQMD has authority for reducing emissions from stationary sources and has limited authority over mobile sources and consumer products. In 1987, State Senate Bill 151 gave SCAQMD substantial new authority to develop transportation control measures and rules for indirect sources of air pollutants, such as shopping centers, stadiums, and other facilities that attract large volumes of motor vehicles. SCAQMD also is required to develop additional programs and regulations for increasing commuter ridesharing and limiting heavy truck traffic on urban freeways during peak commute hours.

The CAAA requires that clean air plans be updated periodically for all non-attainment areas. The California Clean Air Act (CCAA; Sher-AB-2595) similarly requires development and periodic revision of a plan to meet SAAQS. A revised AQMP for federal standards was prepared in February, 1997. The CCAA most recent plan update was due at the end of 2000. The revised AQMP was prepared early in 1997. It contained an attainment plan for PM-10 for the first time ever, and was designed to meet both federal and state planning requirements.

The 1997 AQMP/SIP was challenged in court as not meeting Clean Air Act deadlines for air quality improvement. The plan was sent back to SCAQMD/SCAG to accelerate deadlines and/or establish additional control programs. In 1999, 13 additional measures were added to the plan. The 1999 SIP Amendments (1997 Plan + 13 changes) were approved by EPA in 2000 as the current basinwide clean air plan.

TABLE 2

Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards		Federal Standards		
		Concentration	Method	Primary	Secondary	Method
Ozone (O ₃)	1 Hour	0.09 ppm (180 µg/m ³)	Ultraviolet Photometry	0.12 ppm (235 µg/m ³)	Same as Primary Standard	Ethylene Chemiluminescence
	8 Hour	—		0.08 ppm (157 µg/m ³)

Method: ARB Method V (8/18/89).		No Federal Standards		
Sulfates	24 Hour	25 µg/m ³	Turbidimetric Barium Sulfate-AIHL Method 61 (2/76)			
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m ³)	Cadmium Hydroxide STRactan			

As part of the AQMP, SCAQMD structures most of its pollution control programs through its Rules and Regulations. SCAQMD's Rules and Regulations include rules that apply to project construction or operation. For a residential development such as the proposed Chatsworth Ridge Estates project, few of the SCAQMD rules apply to a source generating mainly mobile source emissions. Any air district rules therefore apply mainly to construction. Rules that may apply to construction of the proposed project include: Rule 401 - Visible Emissions; Rule 402 - Nuisance Emissions; and Rule 403 - Fugitive Dust.

o **Southern California Association of Governments**

Southern California Association of Governments (SCAG) is responsible for adopting regional growth forecasts and the Regional Transportation Improvement Program (RTIP). Local governments are responsible for implementing suggested transportation and land use measures. These plans and forecasts are incorporated into SCAG's Regional Comprehensive Plan (SCAG 1994) which is thus directly linked to the AQMP. Project conformity with the regional growth forecast, as well as implementation of any air quality planning measures applicable on a project-specific basis, are considered necessary conditions to support a finding of a less than significant regional air quality impact from any general development project.

General development such as Chatsworth Ridge Estates does not relate directly to the AQMP/SIP because there are no specific measures in these documents that relate directly to overall growth. The air quality plan does have transportation and land use measures designed to reduce vehicle miles traveled (VMT) and vehicle trips (VT) generated. Land use patterns that concentrate housing, employment, goods and services, recreation, etc. into a single geographic area promote VMT/VT reduction. Such patterns are considered air quality positive and thus consistent with the AQMP.

Los Angeles County, in its land use planning authority, has developed air quality strategies that adapt the regional VMT/VT objectives to county-wide opportunities and constraints. As with the regional plan, the County's air quality program focuses on the integration of multiple types of land uses. The plan is designed to encourage the use of alternatives to the single occupant vehicle, to shift travel to off-peak periods, and to promote development patterns that maintain a favorable jobs/housing balance. As with the regional plan, it is not possible to isolate the air quality role of one single development such as Chatsworth Ridge Estates without considering its interaction with the entire existing pattern of development and associated infrastructure.

AIR QUALITY IMPACT

Residential developments such as that proposed for the Chatsworth Ridge Estates project potentially impact air quality almost exclusively through increased automotive emissions. Any single project typically does not cause enough traffic and associated air pollutants to be generated as to individually threaten clean air standards. It is the cumulative effect of hundreds of such developments that causes the small incremental impact from any one development to become cumulatively significant. Minor secondary emissions during construction, from increased fossil-fueled energy utilization and from small miscellaneous sources will also be generated, but these are usually much smaller in both duration and volume than the mobile source emissions.

Standards of Significance

Many air quality impacts which derive from dispersed mobile sources, i.e., the dominant pollution generators in the basin, often occur hours later and miles away after photochemical processes have converted primary exhaust pollutants into secondary contaminants such as ozone. The incremental regional air quality impact of an individual project is generally immeasurably small. The SCAQMD has therefore developed suggested significance thresholds based on the volume of pollution emitted rather than on actual ambient air quality because the direct air quality impact of a project is not quantifiable on a regional scale. The 1993 SCAQMD CEQA Air Quality Handbook states that any projects in the SCAB with daily emissions that exceed any of the following thresholds should be considered as having an individually and cumulatively significant air quality impact:

- 55 lbs per day of ROC (75 lbs/day during construction)
- 55 lbs per day of NO_x (100 lbs/day during construction)
- 550 lbs per day of CO
- 150 lbs per day of PM-10
- 150 lbs per day of SO_x

These thresholds do not take into account several important considerations, namely:

1. Emission levels from one large project may exceed thresholds while those from numerous smaller projects with identical emissions might not, even though the regional impact is the same.
2. Large developments have a greater opportunity to effectively implement transportation control measures (TCMs) because of a greater potential participant pool in trip/VMT diversion programs.
3. Project-related emissions and their regional impact may already have been incorporated into regional growth projections.
4. Emissions generated by project traffic have essentially the same regional air quality impact as if they were released in any other nearby community. If the anticipated demand for residential growth is not met at the project site but in some other nearby locality, the no-project alternative will have basically the same regional air quality impact.

These considerations support a finding of a less-than-significant impact, even if the SCAQMD advisory thresholds are exceeded. Alternately, the Lead Agency may make a finding of a significant impact for projects exceeding the SCAQMD thresholds, but use as many of the above criteria in a statement of overriding considerations as are applicable.

Additional indicators are listed in the SCAQMD Handbook that should be used as screening criteria to evaluate the need for further analysis with respect to air quality. Whenever possible, the project should be evaluated in a quantitative analysis; otherwise a qualitative analysis is appropriate. The additional indicators are as follows:

- Project could interfere with the attainment of the federal or State ambient air quality standards by either violating or contributing to an existing or projected air quality violation;
- Project could result in population increases within the regional statistical area which would be in excess of that projected in the AQMP;
- Project could generate vehicle trips that cause a CO hot spot;
- Project might have the potential to create or be subjected to objectionable odors;
- Project could have hazardous materials on site and could result in an accidental release of air toxic emissions;

- Project could emit an air toxic contaminant regulated by District rules or that is on a federal or State air toxic list;
- Project could involve disposal of hazardous waste;
- Project could be occupied by sensitive receptors near a facility that emits air toxics or near CO hot spots;
- Project could emit carcinogenic air contaminants that could pose a cancer risk.

For the conversion to residential use of the Devil Canyon area from low-intensity open space such as the project site, secondary significance criteria are rarely triggered. Potential impact significance thus relates mainly to the SCAQMD CEQA Handbook numerical emissions thresholds identified above.

Project-Related Sources of Potential Impact

Intensification of land uses in Los Angeles County potentially impacts ambient air quality on two scales of motion. As cars drive throughout Southern California, the small incremental contribution to the basin air pollution burden from any single vehicle is added to that from several million other vehicles. The impact from the project, even if it generates a significant number of new vehicle trips, is very small on a regional scale. Basinwide impact significance is, therefore, addressed in terms of project compatibility with regional air quality plans. If any given project or plan has been properly incorporated into basinwide growth projections which are the basis for regional air quality/transportation planning, then there would be no potential impact significance due to air quality planning inconsistency.

Locally, changes in the location of any collection of automotive sources, or changes in the number of vehicles or travel speeds may impact the microscale air quality around any given development site. Traffic increases not only contribute air pollutants in direct proportion to their cumulative percentage of traffic volume growth, but they may slow all existing traffic to slower, more inefficient travel speeds. The development traffic/air quality impact is thus potentially compounded.

Temporary construction activity emissions will occur during project buildout. Such emissions include on-site generation of dust and equipment exhaust, and off-site emissions from construction employee commuting and/or trucks delivering building materials.

Because of their temporary nature, air quality impacts from construction have often been considered as individually less than significant if the activities comply with all applicable SCAQMD rules. Also, construction activity emissions are difficult to quantify, since the exact type and amount of equipment that will be used or the acreage that may be disturbed on any given day in the future is not known with any reasonable certainty. The emphasis in environmental documents relative to construction activity emission impacts has therefore been to minimize the emissions as fully as possible through comprehensive mitigation even if the precise amount of emissions can not be precisely quantified.

Construction Activity Impacts

Dust is normally the primary concern during construction of new buildings and infrastructure. Because such emissions are not amenable to collection and discharge through a controlled source, they are called "fugitive emissions." Emission rates vary as a function of many parameters (soil silt, soil moisture, wind speed, area disturbed, number of vehicles, depth of disturbance or excavation, etc.). Regulatory agencies typically use one universal factor based on the area disturbed. This factor assumes average values of soil moisture, silt content and wind speed. This assumption may or may not be valid, depending upon site-specific distributions of the above parameters. As noted previously, emissions estimation for project-specific fugitive dust sources is therefore characterized by a considerable degree of imprecision.

The PM-10 fraction of fugitive dust emissions are predicted to be around 55 pounds per day per acre disturbed in the absence of any dust control measures being applied (SCAQMD Handbook, Table 9-2). Mandatory measures required by South Coast AQMD Rule 403 (Fugitive Dust) are generally assumed to reduce this rate by approximately 50%. Average daily PM-10 emissions during site grading and other disturbance are stated in the SCAQMD Handbook to be 26.4 pounds/acre. This estimate is based upon required dust control measures in effect in 1993 when the AQMD CEQA Air Quality Handbook was prepared. Rule 403 was subsequently revised to require use of a greater array of fugitive dust control on construction projects. Use of enhanced dust control procedures such as continual soil wetting, use of supplemental binders, early paving, etc. can achieve a substantially higher PM-10 control efficiency. With the use of currently mandated Best Available Control Measures (BACMs) for dust control, a reduced emission rate of around 10.2 pounds per acre is generally attainable.

Use of "standard" daily PM-10 emission factors allows for the simultaneous disturbance of around 5.7 acres to generate a potentially significant emission level of 150 pounds per day

recommended to be designated as having a temporarily significant impact in the SCAQMD Handbook ($150 \div 26.4 \approx 5.7$). If BACMs are implemented, as much as 15 acres of the project site could be under disturbance to maintain a less than significant daily PM-10 emission rate.

Maximum daily grading capacity has been estimated at 30,000 cubic yards per day by the project construction supervisor. The average depth of cut or fill has been estimated at one yard for purposes of calculating a daily disturbance area for dust calculation purposes. The daily "footprint" during maximum grading would be 6.2 acres of cut and 6.2 acres of fill, or 12.4 acres per day.

Peak daily PM-10 emissions, relative to the 150 pound per day significance threshold, are calculated as follows:

Standard Mitigation	-	12.4 ac X 26.4 lb/ac/day	=	327 lb/day
With Use of BACMs	-	12.4 ac X 10.2 lb/ac/day	=	126 lb/day

With the use of BACMs, peak grading activity days will experience PM-10 emissions that are below the identified significance threshold. A menu of dust control measures that constitute BACMs is included in the mitigation recommendations for this project. Regardless of emissions magnitude, it should be noted that construction activity dust does not necessarily have any adverse health impacts. Adoption of a new air quality standard for ultra-small diameter particulates has recently occurred at the federal level. This new standard has implications for construction fugitive dust for two reasons, namely,

1. Human health effects from particulate inhalation are mainly related to very small diameter, chemically active material, and,
2. Construction fugitive dust contains almost no ultra-fine particulates (2.5 micron diameter or smaller, called "PM-2.5"), and the dust material is comprised mainly of chemically inert silicates.

Construction activities generate negligible amounts of PM-2.5, and the very small fraction that is created is typically not chemically/biologically reactive in human lung tissue. From a human health perspective, construction activity dust generation has a less than significant air quality impact.

Observable construction activity dust impacts derive almost exclusively from the largest diameter material that has a residence time of only a few seconds. These large particulates quickly settle out on parked cars, landscaping, outdoor furniture and other horizontal surfaces. The primary zone of impact from heavy particulates, however, is less than 100 feet from the source. The nearest sensitive uses will be generally well beyond 100 feet from any construction disturbance area. The distance buffer between the point of disturbance and the nearest residence is thus normally adequate to add only minimally to any local soiling effects.

In addition to PM-10 emissions, construction will entail the use of internal combustion engines to power on-road trucks and off-road mobile, semi-mobile and semi-stationary equipment. Such sources are mainly diesel-powered and are often poorly regulated in terms of allowable emission levels. Off-road sources are sometimes not well maintained because there is no regulatory mechanism to enforce efficient combustion as there is for on-road sources. Construction activities and associated emissions will be heaviest during mass grading activities. A "typical" construction fleet of 5 scrapers, a dozer, a grader, a loader and a water truck were assumed operating on a single day. The resulting maximum daily air emissions relative to the SCAQMD construction activity significance thresholds are shown in Table 3.

Average daily NO_x emissions may exceed the threshold. However, these estimates are based upon construction equipment that is 20-30 years old. New equipment will have lower NO_x emissions in response to new state-wide emission standards for off-road construction equipment. As newer equipment is used in later phases of project development, the NO_x emission rate will decrease. The use of periodic low-NO_x tune-ups for on-site equipment can also reduce the NO_x levels. With newer equipment than assumed and with a routine NO_x emissions abatement program, NO_x emissions can be reduced to just under the significance threshold. All other pollutants will be at sub-threshold levels with a large margin of safety. However, the non-attainment status of the airshed dictates that reasonable and feasible available control measures to minimize construction equipment exhaust emissions for all pollutants should be implemented even if thresholds are not exceeded.

Construction activities are concentrated at the construction site, but they also spill over into the adjacent community. Vehicles track dirt off-site, lane closures create congestion on public roadways and construction worker vehicles and supply trucks compete with the general public for sometimes inadequate roadway capacity. Trucks are often left idling near off-site sensitive receptors while waiting to load or unload. Each of these small impacts may become substantial when summed over all basinwide construction

1. The first part of the document discusses the importance of maintaining accurate records of all transactions and activities. This is essential for ensuring transparency and accountability in the organization's operations.

activities. As with the on-site impacts, a heightened level of impact mitigation will need to be implemented to maintain an overall tolerable level of impact from project construction activities.

Operational Impacts

By far, the greatest project-related air quality concern centers on the 4,422 new vehicle trips per day that will be generated at project completion. For typical Los Angeles County residential trip lengths, additional vehicle travel from project implementation will be about 40,000 vehicle miles traveled (VMT).

Secondary impact potential will derive from energy consumption in power plants or on-site heaters, stoves, water heaters, etc. General development also creates miscellaneous emissions from a variety of sources such as cleaning products, landscaping equipment, or fireplaces, and also contributes to off-site emissions at restaurants, gas stations, dry cleaners, or sand and gravel plants. Except for more readily quantifiable energy consumption (stationary sources), many of the small miscellaneous sources are typically not quantified on a single project basis. These small sources, however, are non-negligible when minute individual contributions are summed over millions of Southern California residences. They further attest to the conclusion that overall anticipated growth is a substantial impediment to the attainment of regional clean air standards.

The California ARB has developed a land use and air pollution emissions computer model that allows one to reliably calculate the daily emissions increase associated with the proposed project. This model, called URBEMIS7G, was run for a project build-out year of 2002. The calculation was repeated for the years 2005 and 2010 to show how a cleaner future vehicle fleet will progressively reduce the project's impact on future air quality. Stationary source (energy consumption) emissions were not calculated because electricity deregulation has broken any direct linkage between the location where electricity is used and the location of the power source where it was generated. The project-related mobile source emissions burden, along with a comparison of SCAQMD recommended significance thresholds, is shown in Table 4.

At project buildout, project-related mobile source emissions will be below the AQMD's suggested significance threshold for all pollutants. With continued future vehicular improvements, the mobile source emissions will constitute a declining share of the regional inventory. By 2010, project-related NO_x will have decreased to 61 percent of the significance threshold and other

Source: URBEMIS7G Computer Model; Output in Appendix

pollutants will be an even lesser percentage of the adopted significance level. Minor additional emissions reductions may also result from the availability of public transportation and other trip-reduction options (increased telecommuting, etc.). These small offsets would further increase the margin of safety between the project mobile source emissions burden and the SCAQMD significance threshold.

In addition to regional air quality concerns which focus on the photochemical conversion of air pollution emissions to more harmful forms, vehicular exhaust may impact air quality immediately adjacent to the roadway travel lanes. Such impacts occur during periods of maximum traffic congestion and minimum atmospheric dispersion. Microscale air quality impacts are a potential problem because some intersections are forecast to operate at congested levels of service at area buildout unless mitigated.

In order to determine whether any possible traffic congestion may contribute to localized air pollution standard violations, a screening procedure based upon the California roadway dispersion model CALINE4 was run on several roadways surrounding the project area. Carbon monoxide (CO) was used as an indicator pollutant to determine "hot spot" potential. Rush hour traffic was combined with minimum dispersion conditions in order to create a theoretical worst-case impact estimate. Calculations were made for the projected project buildout (2005). A possible one-hour CO "hot spot" was presumed to possibly occur if the local contribution plus the worst-case regional background level of 8 ppm (2000) exceeded the one-hour standard of 20 ppm. A local concentration exceeding 12 ppm thus could create a temporary "hot spot." The results of these calculations are shown in Table 5.

A possible existing microscale violations of standards are seen in Table 5 to occur at the DeSoto Avenue and Chatsworth Street intersection because of high traffic volumes and LOS=F intersection performance. Continued vehicular emissions reductions and only small additional traffic increases will slightly reduce the CO "hot spot" potential at this intersection by 2005.

Table 5 shows that the maximum project-related CO increment above the related projects scenario is 1.2 ppm at the Topanga Canyon Blvd./SR-118 (WB) Ramp intersection during the peak traffic hour scenario because the project will create a measurable worsening of the level of service. This 1.2 ppm impact will be reduced to essentially zero with recommended traffic mitigation (lane restriping). All other project-related microscale CO increments are 0.1 ppm or less. This small increment will not cause the

hourly standard to be exceeded. The one-hour CO standard is 20 ppm. The project increment is less than one percent of the standard. All with-project CO increments are dominated by the no-project area growth of traffic and congestion. Microscale air quality impacts are not considered significant.

MITIGATION

The proposed development will not contribute to regional air quality degradation by virtue of not exceeding SCAQMD significance thresholds. Grading activity may cause PM-10 emissions to exceed the daily significance threshold unless best available control measures (BACMs) are used. Construction activity equipment emissions may also exceed significance thresholds unless mitigated. Potentially significant construction emissions, coupled with the overall non-attainment status of the airshed, place a special responsibility on project proponents and local regulatory agencies to develop effective impact mitigation even for all emissions whether they exceed significance thresholds or not.

Effective emissions reduction of mobile source emissions will require a unified transportation system management (TSM) approach where a wide variety of transportation control measures (TCMs) are integrated into a comprehensive system of procedures and goals. An effective TSM program as a means for reducing vehicular traffic and its associated environmental effects (air pollution, noise, energy consumption, etc.) is difficult to achieve in practice because of the dependence on the low (mainly single) occupant vehicle as the primary means of transportation.

On a project-specific basis, the number of options to reduce vehicular emissions that can be implemented by an individual developer are limited. With only an assumed minimal use of transit, all mobile source emissions are predicted to be below SCAQMD significance thresholds. Additional mitigation would not be required. However, because of the non-attainment status of the airshed, use of all available mitigation is nevertheless encouraged regardless of impact significance. Recommended developer-sponsored measures include the following:

1. Providing an attractive pedestrian environment,
2. Incorporating bicycle trails and interconnections,
3. Building homes that exceed minimum statewide energy construction requirements,
4. Including residential design features that encourage trip elimination or trip diversion to alternative transportation:
 - a. Pre-wired for various telecommunications systems access for in-home offices
 - b. Pre-wired for 220V electric vehicle charging systems.

With optimum incorporation of these measures, the daily trip elimination/diversion, or the level of daily on-site energy consumption, can be reduced by perhaps two to three percent. Such a reduction from developer-promoted air pollution emissions mitigation would further increase the margin of safety between project-related mobile source emissions and the SCAQMD threshold.

Construction activity impact mitigation should also be incorporated into the development approval process. Specific measures should include:

1. Use of watering for dust control during clearing, grading and construction using groundwater from on-site wells. Availability of brackish or reclaimed water sources should be investigated. Soil disturbance should be terminated when high winds (>25 mph) make dust control extremely difficult.
2. Developing a dust control program to supplement the routine watering that constitutes best available control measures (BACMs) in excess of any minimum SCAQMD Rule 403 requirements. BACMs that may be adopted and integrated an enhanced dust control program might include hydroseeding previously disturbed areas while awaiting construction, adding chemical binders or surfactants to increase the effectiveness of watering, early paving or chip sealing of roads, enforcing reduced travel speeds (15 mph) on unpaved surfaces and/or sand fences and perimeter sandbags.
3. Minimization of construction interference with regional non-project traffic movement. Measures recommended for inclusion are:
 - a. Scheduling receipt of construction materials to non-peak travel periods.
 - b. Routing construction traffic through areas of least impact sensitivity.
 - c. Limiting lane closures and detours to off-peak travel periods.
 - d. Providing ride-share incentives for contractor and subcontractor personnel.
4. Reducing "spill-over" effects by preventing soil erosion, washing vehicles entering public roadways from dirt off-road project areas, and washing/sweeping project access to public roadways on an adequate schedule.

5. Requiring emissions control from on-site equipment through a routine mandatory program of low-emissions tune-ups, and requiring use of off-road equipment with engine manufacture dates of 1991 or later to insure that exhaust emissions have been reduced as much as possible with more current engine technology.
6. Limiting grading/soil disturbance to as small an area as practical at any one time. If the maximum daily disturbance footprint can not be effectively limited to no more than 15 acres, significance of peak daily PM-10 emissions in excess of SCAQMD thresholds needs to be acknowledged in a statement of overriding considerations.
7. Limiting the application of architectural surface treatments (i.e., paint, etc.) to average no more than two houses per day over the project buildout lifetime.

The technology does not exist to construct 484 dwelling units in a semi-arid climate without creating some dust and equipment exhaust. These temporary impacts can, however, be reduced to a less-than-significant level if a commitment is made to pursue available impact mitigation as aggressively as possible. With effective mitigation, the degree of "excess" emissions can be reduced to a less-than-significant level.

COMPARISON OF ALTERNATIVES - AIR QUALITY

Air quality impacts derive from the number of units developed, (operational trips generated) and from the total project disturbance footprint (construction emissions). Construction activity emissions have been calculated based upon a worst-case day of 30,000 cubic yards of cut and fill. That practical limit would exist for each alternative. The only construction activity impact difference for any "build" alternative is that these construction emissions (dust and/or equipment exhaust) would occur for a slightly longer period for 657 units, or for 538 homes built in Chatsworth Ridge.

Operation (traffic) emissions were calculated to be at slightly below the SCAQMD threshold for the proposed project. Maximum microscale air quality impacts from the proposed project were 0.1 ppm or less at any intersection with possible CO "hot spots." This constitutes 0.5 percent of the most stringent one-hour CO standard. Even if this impact level were doubled for a higher intensity development alternative, it would still be only one percent of the standard. The comparison of alternatives thus focuses only on the differences in regional vehicular pollution emissions.

Alternative 1 would develop 657 units. This represents a 36 percent increase in the number of units analyzed for the preferred alternative. An increase in the operational impacts of 36 percent leads to the following daily emissions relative to the SCAQMD CEQA Air Quality Handbook thresholds:

PERCENT OF SCAQMD THRESHOLD

<u>Pollutant</u>	<u>Operations*</u>	
	<u>Proposed Project*</u>	<u>Altern. 1</u>
CO	57%	77%
NO _x	79%	<u>107%</u>
PM-10	21%	29%
ROG	77%	<u>105%</u>

* - project buildout year = 2005

Underlined values exceed SCAQMD thresholds.

Implementation of this alternative would cause emissions of NO_x and ROG to slightly exceed SCAQMD thresholds that do not exceed thresholds with the proposed project. This alternative would be less preferable than the proposed project unless buildout were delayed until 2006 or 2007 when cleaner cars would offset the small (5-7%) amount of excess emissions predicted for a year 2005 buildout for this alternative.

Alternative 2 would develop 538 units. This represents a 10% increase in the number of units analyzed for the preferred 484-unit alternative. An increase in the operational impacts of 10 percent leads to the following daily emissions relative to the SCAQMD CEQA Air Quality Handbook thresholds:

<u>Pollutant</u>	<u>PERCENT OF SCAQMD THRESHOLD</u>	
	<u>Proposed Project</u>	<u>Altern. 2</u>
CO	57%	62%
NO _x	79%	87%
PM-10	21%	23%
ROG	77%	85%

* - project buildout year = 2005

Implementation of this alternative would increase all emissions by ten percent compared to the proposed project. A ten percent increase would not cause emissions to exceed SCAQMD thresholds.

The no-project alternative would not avoid any significant impacts compared to the proposed project since project impacts (with mitigation) would be mitigated to less-than-significant levels. Because the same level of residential growth would likely occur elsewhere in the region, basinwide air quality would be unaffected by selection of this alternative.

1.0 INTRODUCTION

1.1 PROJECT OVERVIEW & DESCRIPTION

The project applicant, Presidio Chatsworth Partners, LLC, proposes to develop an approximate 485 unit single-family residential subdivision on about 235 acres of mostly undeveloped land within the northwestern San Fernando Valley area of Los Angeles County. A portion of the project site with natural communities will be preserved as natural open space. The project site does not occur within the County of Los Angeles Significant Ecological Areas (SEAs) or Environmentally Sensitive Habitat Areas (ESHAs).

Glenn Lukos Associates, Inc. (GLA) was retained by Presidio Chatsworth Partners, LLC to conduct biological surveys of the project (Chatsworth Ridge Estates) study area and to prepare a biological technical report. GLA's assessment is based upon field surveys conducted from March to August 1998, June 1999, April through July 2000, November and December 2000, and May through July 2001.¹ Envicom Corporation also conducted focused botanical surveys in the summer of 2001 (Appendix D).

This biological technical report provides a description of vegetation communities, wildlife and U.S. Army Corps of Engineers (Corps) and California Department of Fish and Game (CDFG) jurisdictions located on the project site. This document assesses the potential for the project site to support sensitive plant and wildlife species as well as wildlife movement corridors. In addition, this report evaluates project impacts and provides mitigation measures designed to reduce project impacts to a level that is less than significant.

1.2 SITE LOCATION & CONDITIONS

The Chatsworth Ridge Estates project in Los Angeles County, [*Exhibit 1*], comprises approximately 230.58 acres of undeveloped land and is depicted on the U.S. Geological Survey (USGS) 7.5 minute topographic map Oat Mountain, California (dated 1952 and photo revised in 1969) [*Exhibit 2*]. The proposed project site is located in an unincorporated section of Los Angeles County within the northwestern San Fernando Valley area in the south-facing

¹ Following completion of the year 2000 focused surveys, the project applicant acquired an additional 13 acres adjacent to the project site. Field surveys for this area were conducted in November and December 2000 and May through July 2001.

foothills of Santa Susana Mountains in an area known as Chatsworth. The elevation of the site ranges from approximately 1,200 feet above mean sea level (MSL) in the southeastern section to approximately 1,560 feet above MSL in the northern section.

The topography of the project study area consists of north-south ridges, canyons, and a relatively flat mesa characterized by dry washes and sandstone rock outcrops. Soils on the site consist of sandy soils weathered from sandstone bedrock, along with alluvial soils in drainages. The site supports various habitats and vegetation communities. Native vegetation communities include chamise chaparral, coastal sage scrub, coast live oak woodland, and willow woodland. Non-native vegetation communities include non-native grasslands and eucalyptus groves. Portions of the property were previously developed and/or graded for homes, roads, and equestrian trails.

Lands to the north and east of the project site are undeveloped. Although the land immediately adjacent to the westerly boundary of the site is vacant, an existing multi-family residential complex is located approximately 1/4 mile from the project site, and two existing single family detached residential communities are located approximately 1/2 mile westerly of the project site. Development along the southern boundary of the site consists of single family dwelling units and the Ronald Reagan Freeway (SR-118).

2.0 SURVEY METHODS

GLA conducted biological field surveys on the approximate 230.58-acre site during March to August 1998, June 1999, April through July 2000, and November through December 2000, and May through July 2001.¹ Envicom Corporation also conducted focused botanical surveys in the summer of 2001. Field studies focused on the following objectives: (1) identify and map vegetation communities; (2) delineation for Corps and CDFG jurisdictions; (3) list all observed plant and wildlife species; (4) determine the potential for the existing habitats to support sensitive plant and wildlife species as listed by U.S. Fish and Wildlife Service (USFWS), CDFG and the California Native Plant Society (CNPS). Observations of all plant and wildlife species were recorded.

A review of literature and databases were utilized from USFWS, CDFG, field guides, California Natural Diversity Database (CNDDDB), CNPS (Skinner and Pavlik, 1994), and other pertinent literature. A search of the CNDDDB for the Oat Mountain Quadrangle resulted in records for several sensitive species and habitats with the potential to occur in the area. The references are summarized below:

Plants: CNDDDB (1999), Skinner and Pavlik (1994), CDFG(1999)

Wildlife: CNDDDB (1999); USFWS (1992, 1999); CDFG (1988, 1990a, 1990b, and 1999)

Habitats: CNDDDB (1999); CDFG (1999)

Based upon the field studies, literature and database review, GLA determined focused surveys for sensitive species potentially occurring on the project site were required. The focused surveys for potential sensitive plant species include:

Braunton's milkvetch (*Astragalus brauntonii*)

Nevin's barberry (*Berberis nevinii*)

Catalina mariposa lily (*Calochortus catalinae*)

Slender mariposa lily (*Calochortus clavatus* var. *gracilis*)

Plummer's mariposa lily (*Calochortus plummerae*)

San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*)

¹ Following completion of the year 2000 focused surveys, the project applicant acquired an additional 13 acres adjacent to the project site. Field surveys for this area were conducted in November and December 2000 and May through July of 2001.

Slender-horned spineflower (*Dodecahema leptoceras*)
Santa Susana tarplant (*Hemizonia minthornii*)
Southern California black walnut (*Juglans californica* var. *californica*)
Robinson's pepper grass (*Lepidium virginicum* var. *robinsonii*)
Ocellated Humboldt lily (*Lilium humboldtii* ssp. *ocellatum*)
Fish's milkwort (*Polygala cornuta* var. *fishiae*)
Coast live oak trees (*Quercus agrifolia*)

The focused surveys for potential sensitive wildlife species include:

California red-legged frog (*Rana aurora draytonii*)
San Diego horned lizard (*Phrynosoma coronatum blainvillei*)
Two-Striped Garter Snake (*Thamnophis hammondi*)
Cooper's hawk (*Accipiter cooperii*)
Ashy rufous-crowned sparrow (*Aimophila ruficeps canescens*)
Western yellow warbler (*Dendroica petechia brewsteri*)
Southwestern willow flycatcher (*Empidonax traillii extimus*)
Coastal California gnatcatcher (*Polioptila californica californica*)
Least Bell's vireo (*Vireo billi pusillus*)

As noted above, focused surveys were conducted from March through August 1998, April through July 2000, and May through July 2001.² Envicom Corporation also conducted focused botanical surveys in the summer of 2001.

2.1 VEGETATION COMMUNITIES

Vegetation associations were mapped in the field directly onto clear acetate overlain on an 80-scale black and white aerial photograph of the site. Vegetation associations were mapped based upon descriptions provided by Holland (1986) with, as appropriate, modifications to more accurately characterize site conditions. Vegetation mapping was initially conducted in March of 1998 and refined during subsequent field visits through December of 2000.

² The year 2001 focused spring surveys covered the 13-acre parcel acquired in 2000, following completion of the year 2000 focused spring surveys.

2.2 CORPS & CDFG JURISDICTION

Delineation for Corps and CDFG jurisdiction were conducted in the field and recorded on site topography maps. Prior to beginning the field delineation, an 80-scale black and white aerial photograph, an 80-scale topographic base map of the property, and the previously cited USGS topographic map were examined to determine the locations of potential areas of Corps/CDFG jurisdiction. Suspected jurisdictional areas were field checked for the presence of definable channels and/or wetland vegetation, soils and hydrology. Suspected wetland habitats on the site were evaluated using the methodology set forth in the *U.S. Army Corps of Engineers Wetland Delineation Manual*³ (Wetland Manual). While in the field the jurisdictional area was recorded onto an 80-scale color aerial photograph using visible landmarks. Other data were recorded onto wetland data sheets.

The two blue-line drainages on the project site (which were not scheduled to be impacted by proposed development) were delineated only by review of an 80-scale aerial photograph and limited field investigation. Therefore, the Corps and CDFG jurisdictional areas in Browns and Devil Canyons are given as estimates. Portions of Devil Canyon were dedicated to the Santa Monica Mountains Conservancy; Browns Canyon will be maintained as open space. The Soil Conservation Service (SCS) was used to determine the various soil types as occurring in the general vicinity of the project site.

2.3 PLANTS

Plant species encountered during the field surveys were identified and recorded following the guidelines adopted by CNPS and CDFG, as described by Nelson (1994). Scientific nomenclature and common names used in this report follow Hickman (1993). When not available in Hickman, common names are taken from McAuley (1985), Roberts (1998), or Beauchamp (1986). A complete list of the plant species observed during the surveys is provided in Appendix A.

Focused surveys were conducted for the following sensitive plant species potentially occurring on the project site: Braunton's milkvetch (*Astragalus brauntonii*), Nevin's barberry (*Berberis nevinii*), Catalina mariposa lily (*Calochortus catalinae*), slender mariposa lily (*calochortus*

³ Environmental Laboratory. 1987. *Corps of Engineers Wetlands Delineation Manual*, Technical Report Y-87-1, U.S. Army Engineer Waterways Experimental Station, Vicksburg, Mississippi.

clavatus var. *gracilis*), San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*), Plummer's mariposa lily (*Calochortus plummerae*), Slender-horned spineflower (*Dodecahema leptoceras*), Santa Susana tarplant (*Hemizonia minthornii*), southern California black walnut (*Juglans californica* var. *californica*), Robinson's pepper grass (*Lepidium virginicum* var. *robinsonii*), ocellated Humboldt lily (*Lilium humboldtii* ssp. *ocellatum*), Fish's milkwort (*Phygala cornuta* var. *fishiae*), and coast live oak (*Quercus agrifolia*). The focused botanical surveys were conducted between March and August 1998, April and July 2000, and May through July of 2001. Envicom Corporation also conducted focused botanical surveys in the summer of 2001.

Oak trees were tagged and mapped by L. Newman Design Group, Inc. (LNDG) in 1998 and 2000 to determine the conditions of the trees and provide guidance to minimize any encroachments upon the preserved trees. A total of 353 oak trees were identified on the project site. The results from the oak tree surveys are documented in a separate report also prepared by LNDG entitled *Oak Tree Survey Report* dated December 20, 2000.

2.4 WILDLIFE

Wildlife species were detected and recorded during field surveys by sight, calls, tracks, scat, nests or other signs. Scientific nomenclature and common names for vertebrate species referred to in this report follow Collins (1997) for amphibians and reptiles, Jones, et al. (1992) for mammals and AOU Check-list (1998) for birds. A complete list of wildlife species observed or detected onsite is provided in Appendix A.

Surveys were conducted for the following sensitive wildlife species potentially occurring on the project site: Cooper's hawk (*Accipiter cooperii*), ashy-rufous crowned sparrow (*Aimophila ruficeps canescens*), western yellow warbler (*Dendroica petechia brewsteri*), southwestern willow flycatcher (*Empidonax traillii extimus*), coastal California gnatcatcher (*Polioptila californica californica*), California red-legged frog (*Rana aurora draytonii*), two-striped garter snake (*Thamnophis hammondi*), and least Bell's vireo (*Vireo billi pusillus*). Specific survey protocol is required for southwestern willow flycatcher, coastal California gnatcatcher, California red-legged frog, and least Bell's vireo.

2.4.1 SOUTHWESTERN WILLOW FLYCATCHER

Surveys for the southwestern willow flycatcher were conducted according to the guidelines issued by the USFWS (1997). These guidelines stipulate that three visits be conducted within areas of suitable habitat, within the following survey windows: (1) May 15 through 31; (2) June 1 through 21; and (3) June 22 through July 10. Protocol surveys were performed by biologists Stephen J. Myers (PRT-804203) and Chet McGaugh (PRT-836517) of Campbell BioConsulting.

Surveys were conducted on May 30, June 20, and July 3, 1998. The surveys covered all areas of willow riparian woodland located within the boundaries of the study area. All areas were covered on foot by walking slowly and methodically along the drainages. The presence/absence of southwestern willow flycatcher was determined by identifying all birds by sight and call and conservatively playing taped vocalizations of southwestern willow flycatcher. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 5:40 A.M. to 10:35 A.M. Temperatures ranged from approximately 46 degrees Fahrenheit to 69 degrees Fahrenheit. Wind speeds ranged from zero to three miles per hour during the surveys. A report to Amy Leverett-Henderson of GLA dated July 24, 1998 documents the results of the protocol southwestern willow flycatcher surveys (Appendix B).

The southwestern willow flycatcher surveys were repeated during Summer 2000 by Kurt Campbell (PRT-781485). The surveys covered all areas of willow riparian woodland located within the boundaries of the study area. All areas were covered on foot by walking slowly and methodically along the drainages. The presence/absence of southwestern willow flycatcher was determined by identifying all birds by sight and call, and conservatively playing taped vocalizations of southwestern willow flycatcher. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 5:25 A.M. to 9:30 A.M. Temperatures ranged from approximately 52 degrees Fahrenheit to 73 degrees Fahrenheit. Wind speeds were calm during all surveys. A report to Brad Henderson of GLA dated September 26, 2000 documents the results of the protocol southwestern willow flycatcher surveys (Appendix B).

2.4.2 COASTAL CALIFORNIA GNATCATCHER

Surveys for the coastal California gnatcatcher were conducted according to the guidelines issued by the USFWS (1997). These guidelines stipulate that six visits be conducted by permitted individuals within areas of suitable habitat, with at least seven days between site visits. Field surveys were performed by GLA biologist Amy Leverett-Henderson (PRT-818321).

Coastal California gnatcatcher surveys were conducted on March 30, April 6, 13, 20, 27, and May 4, 1998. The surveys were conducted within all areas of coastal sage scrub/non-native grassland ecotone. The survey area totaled approximately five acres of coastal sage scrub and adjacent chaparral areas. No coastal California gnatcatchers were observed onsite during protocol surveys in 1998. A letter report to Kirk Waln of the USFWS dated June 4, 1998, documents the results of the 1998 protocol coastal California gnatcatcher surveys (Appendix B).

The gnatcatcher surveys were repeated during Spring 2000 by Brad Henderson (TE-020025-0). These surveys were conducted on May 12, 19, 26, June 6, 13, and 20, 2000. A letter report to the USFWS dated August 3, 2000 documents the results of the latest protocol coastal California gnatcatcher surveys (Appendix B).

2.4.3 ARROYO SOUTHWESTERN TOAD

Biologists from GLA conducted a habitat assessment for the arroyo toad in Browns Canyon and Devil Canyon and determined that suitable habitat for this species was not present on within the boundaries of the site. Therefore, focused surveys for the arroyo toad were not performed.

2.4.4 CALIFORNIA RED-LEGGED FROG

Surveys for the California red-legged frog were conducted according to USFWS guidelines (1997). These guidelines stipulate that four visits be conducted, with two during the day and two at night. The surveys were performed by Peter H. Bloom on August 31, September 5, and September 18, 1999. All areas within canyons potentially supporting red-legged frogs were searched. The California red-legged frog surveys were repeated during Spring/Summer 2000 by Brad Henderson and Jeff Ahrens. A letter report to USFWS dated October 7, 1999 and December 27, 2000 documents the results of the protocol surveys for California red-legged frog (Appendix B).

2.4.5 LEAST BELL'S VIREO

Surveys for the least Bell's vireo were conducted according to the guidelines issued by USFWS (1992). These guidelines stipulate that eight visits be conducted within areas of suitable habitat, with at least seven days between site visits between April 1 and July 31. Field surveys were performed by GLA biologist Amy L. Leverett-Henderson and Campbell Bio Consulting under appropriate weather conditions.

The surveys were conducted on June 8, 15, 22, 29, July 6, 13, 20, and 27, 1998. The surveys covered all areas of willow riparian woodland located within the boundaries of the project site. All areas were covered on foot by walking slowly and methodically along the drainage. The presence/absence of least Bell's vireo was determined by identifying all birds by sight and call. No taped least Bell's vireo vocalizations were used. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 5:30 A.M. to 11:00 A.M. Temperatures ranged from approximately 56 degrees Fahrenheit to 70 degrees Fahrenheit. Wind speeds ranged from zero to five miles per hour during the surveys, averaging zero to two miles per hour over the survey period. A letter report to Kirk Waln of

the USFWS dated August 24, 1998 documents the results of the protocol least Bell's vireo surveys (Appendix B).

The least Bell's vireo surveys were repeated during the spring/summer of 2000 by Brad Henderson and Jeff Ahrens. Protocol surveys were conducted on May 2, 12, 22, June 2, 13, 23, July 3, 13, and August 5, 2000. The surveys covered all areas of willow woodland. All surveys were begun within an hour of sunrise and completed before 11:00 A.M., in accordance with USFWS guidelines. All suitable areas were covered on foot by walking slowly and methodically through the riparian habitat. Weather conditions during the surveys were conducive to a high level of bird activity. Temperatures ranged from approximately 51 degrees Fahrenheit to 84 degrees Fahrenheit. Wind speeds ranged from zero to two miles per hour during the surveys, averaging one mile per hour over the survey period. A letter report to Richard Garlinghouse of Presidio Chatsworth Partners LLC dated September 21, 2000 documents the results of the protocol surveys (Appendix B).

2.5 WILDLIFE MOVEMENT CORRIDORS

In addition to observed species, expected wildlife usage of the site was determined according to known habitat preferences of regional wildlife species and knowledge of their relative distributions in the area. The term "wildlife movement corridors" implies a continuous unidirectional movement of individual animals. While wildlife movement corridors may sometimes be utilized in this way, their two most important functions are the long-term dispersal of genetic material between population centers and the maintenance of balanced viable populations. Surveys of wildlife corridors involved similar methods for detecting wildlife species, spotlighting study to observe wildlife that might be utilizing the site but not traversing the usual game trails, and any necessary directed species surveys.

3.0 VEGETATION COMMUNITIES

Several vegetation communities were identified within the project site. Vegetation communities on the project site include chamise chaparral, coastal sage scrub, coast live oak woodland, willow woodland, oak woodland/willow woodland, non-native grassland, and eucalyptus. The extent and location of each vegetation community as mapped is shown in Exhibit 3 and the acreage of each vegetation community is listed in Table 3.1. The plant species occurring and potentially occurring on the site are included in Appendix A.

Table 3.1
Vegetation Communities

Vegetation Communities	Approximate Total Acres
Chamise Chaparral	190.73
Coastal Sage Scrub/Non-Native Grassland	2.39
Coast Live Oak Woodland	5.73
Willow Woodland	9.88
Oak Woodland/Willow Woodland	0.58
Non-native Grassland/Previously Disturbed ^a	7.56
Eucalyptus Grove	0.18
Previously Graded or Developed	13.53
Total	230.58

^a Includes some developed areas.

Source: Glenn Lukos Associates, Inc., 2000.

3.1 CHAMISE CHAPARRAL

Chamise chaparral occupies flat areas and slopes throughout most of the site and is the predominant vegetation association observed at the project site. A total of approximately 190.73 acres of chamise chaparral has been identified on the project site. Chamise (*Adenostoma fasciculatum*) and black sage (*Salvia mellifera*) are the dominant shrubs in this vegetation association. Other shrubs include Mexican elderberry (*Sambucus mexicana*), laurel

sumac (*Malosma laurina*), Our Lord's candle (*Yucca whipplei*), California buckwheat (*Eriogonum fasciculatum*) and deerweed (*Lotus scoparius*). The understory is composed of annuals including non-native tocolote (*Centaurea melitensis*), common cryptantha (*Cryptantha intermedia*), various suncups (*Camissonia* spp.), common catchfly (*Silene gallica*), and various non-native grasses. A special-status plant species, Plummer's mariposa lily (*Calochortus plummerae*) (CNPS List 1B), occurs in open, xeric areas within the chamise chaparral.

3.2 COASTAL SAGE SCRUB/NON-NATIVE GRASSLAND

The total area of coastal sage scrub/non-native grassland identified on the project site is approximately 2.39 acres and is dominated by California sagebrush (*Artemisia californica*), deerweed (*Lotus scoparius*), and California buckwheat. The understory is composed of slender wild oats (*Avena barbata*), tocalote, and other mostly non-native herbaceous species. The coastal sage scrub on-site occurs in a previously graded homestead near the middle of the site, and most likely represents a transitional early-successional vegetation association. As observed in many areas throughout the state (Mooney, 1977), it is likely that this area would gradually be replaced by chaparral species if left undisturbed.

3.3 COAST LIVE OAK WOODLAND

The total area of oak woodland identified on the project site is approximately 5.73 acres with a dominant overstory species being coast live oak (*Quercus agrifolia*). However, individual oak trees are also found in other vegetation associations on the site. Coast live oak woodland is not listed by CDFG as a sensitive vegetation type. However, the County of Los Angeles has identified the habitat as sensitive. The understory includes shrubs such as toyon (*Heteromeles arbutifolia*), southern California black walnut (*Juglans californica* var. *californica*), Mexican elderberry, poison oak (*Toxicodendron diversilobum*), and non-native grasses. Coast live oak woodland on-site was most often observed adjacent to drainages, or on shaded, north-facing slopes.

3.4 WILLOW WOODLAND

The total area of willow woodland identified on the project site is approximately 9.88 acres, and is more or less analogous with "Southern Mixed Riparian Forest" (Holland, 1986). However, because shrubby species rather than large trees dominate many areas, the general name "willow woodland" is used here. Willow woodland (i.e., Southern Mixed Riparian Forest) is ranked as S2.1 ("very threatened") by CDFG due to its small number of occurrences, individuals, and acres. Dominant vegetation within this association includes arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), mule fat (*Baccharis salicifolia*), and Fremont's cottonwood (*Populus fremontii*). Less common overstory species include black cottonwood (*Populus balsamifera* ssp. *trichocarpa*), western sycamore (*Platanus racemosa*), Southern California black walnut, and occasional box elder (*Acer negundo* var. *californicum*). Adjacent mesic areas support scattered stands of coast live oak and its associated understory includes California blackberry (*Rubus ursinus*), poison oak, and mugwort (*Artemisia douglasiana*). This association occurs in areas adjacent to the Devil Canyon drainage, characterized by areas of dense trees as well as more shrubby willow and mule fat in areas prone to stream scouring. The willow woodland has been invaded by non-native giant reed (*Arundo donax*) in parts of lower Devil Canyon.

3.5 OAK WOODLAND/WILLOW WOODLAND

This association is characterized by small stands dominated by coast live oak and willows (*Salix* spp.) found on stream terraces above Devil Canyon Creek upstream from the Devil Canyon debris dam. This total area on the project site is approximately 0.58 acre.

3.6 NON-NATIVE/PREVIOUSLY DISTURBED

The project site includes approximately 7.56 acres of non-native grassland. Non-native grassland on-site is dominated by slender wild oats (*Avena barbata*), ripgut brome (*Bromus diandrus*), Black mustard (*Brassica nigra*), summer mustard (*Hirschfeldia incana*), common catchfly (*Silene gallica*), and tocolote. The non-native grassland identified on the site occupies approximately 2.20 acres and primarily occurs in areas of past disturbance.

Scattered non-native eucalyptus trees are found in flat areas throughout the site and seedlings have begun to colonize riparian areas. The total area of eucalyptus grove identified on the project site is approximately 0.18 acre. A grove of mature blue gum (*Eucalyptus globulus*) and red gum (*Eucalyptus camaldulensis*) has been planted near Devil Canyon, presumably for fuel wood production. This vegetation association includes an understory typically composed of weedy annual grasses and herbs. Scattered eucalyptus trees occupy most other vegetation associations in several locations.

Previously developed areas that have been graded or repeatedly cleared of vegetation on the project site total approximately 13.53 acres. Some areas exhibit a cover of bare earth and rocks, while other areas are dominated by ruderal plant species, many of which are non-native. Summer mustard, slender wild oat (*Avena barbata*), storksbill (*Erodium* spp.), and cheeseweed (*Malva parviflora*) are common non-natives colonizing these disturbed areas.

4.0 GENERAL WILDLIFE

Most wildlife species are not restricted to a single plant community, occurring instead in several communities, especially those of similar species composition and physical structure. However, some animals, birds, and wide-ranging mammals may utilize an array of dissimilar communities for forage and cover. Most animals found on the project site are common, widespread, and highly adaptable species. Wildlife species recorded by GLA as occurring on the project site result from species that were observed and the presence of diagnostic sign on the site. All wildlife species occurring and potentially occurring on the project site are listed in Appendix A.

4.1 AMPHIBIANS

Amphibians often require a source of standing or flowing water to complete their life cycle. However, some terrestrial species can survive in drier areas by remaining in moist environments found beneath leaf litter and fallen logs, or by burrowing into the soil. These xeric-adapted species conserve moisture by emerging only under conditions of high humidity or when the weather is cool and/or wet.

Willow and oak woodland habitats, as well as permanent flowing water are present on the project site. These areas provide potential habitat for amphibian species adapted to drier conditions, but only minimal potential habitat for species requiring permanent water. Amphibians observed on-site were the Pacific treefrog (*Pseudacris regilla*) and western toad (*Bufo boreas*). Additional amphibian species which could potentially occur on-site include the Pacific slender salamander (*Batrachoseps pacificus*), California newt (*Taricha torosa*), ensatina (*Ensatina eschscholtzii*), arboreal salamander (*Aneides lugubris*), and black-bellied salamander (*Batrachoseps nigriventris*).

4.2 REPTILES

Coastal sage scrub and chaparral communities identified on-site are utilized nearly year-round by a large number of reptile species. Species identified within the scrub and chaparral communities during the site surveys include the western fence lizard (*Sceloporus occidentalis*),

communities during the site surveys include the western fence lizard (*Sceloporus occidentalis*), side-blotched lizard (*Uta stansburiana*), southern alligator lizard (*Gerrhonotus multicarinatus*), western skink (*Eumeces skiltonianus*), California whipsnake (*Masticophis lateralis*), gopher snake (*Pituophis melanoleucus*), western whiptail (*Cnemidophorus tigris*), and western rattlesnake (*Crotalus viridis*). Other reptile species potentially occurring on-site include the Gilbert skink (*Eumeces gilberti*), San Diego banded gecko (*Coleonyx variegatus abbotti*), legless lizard (*Anniella pulchra*), rosy boa (*Lichanura trivirgata*), ringneck snake (*Diadophis punctatus*), racer (*Coluber constrictor*), western patch-nosed snake (*Salvadora hexalepis*), and common kingsnake (*Lampropeltis getulus*).

The reptile species identified within the grassland communities on-site are expected to vary over the course of the year depending on abundance of grasses and availability of cover. Species observed during the site surveys include the western fence lizard, side-blotched lizard, and western rattlesnake. Other reptile species potentially occurring in grassland habitats include the southern alligator lizard, gopher snake, common kingsnake, coachwhip (*Masticophis flagellum*), and night snake (*Hypsiglena torquata*).

Riparian communities tend to exhibit low reptile species diversity. However, reptiles commonly identified near the edge of the intermittent drainages include southern alligator lizard, California whipsnake, side-blotched lizard, and western fence lizard. Other species potentially occurring within or near riparian areas include the Gilbert skink, two-striped garter snake (*Thamnophis hammondi*), and common garter snake (*Thamnophis sirtalis*).

4.3 BIRDS

Birds were the most common vertebrates observed on the project site. The scrub communities present on-site are generally composed of low dense vegetation which provides breeding habitat for resident bird species. Resident bird species observed on the site include the California towhee (*Pipilo crissalis*), wrentit (*Chamaea fasciata*), Bewick's wren (*Thryomanes bewickii*), California quail (*Callipepla californica*), Anna's hummingbird (*Calypte anna*), western scrub-jay (*Aphelocoma coerulescens*), northern mockingbird (*Mimus polyglottos*), and California thrasher (*Toxostoma redivivum*). Migratory species which utilize coastal sage scrub at various times include the white-crowned sparrow (*Zonotrichia leucophrys*), song sparrow (*Melospiza melodia*), Costa's hummingbird (*Calypte costae*), ash-throated flycatcher (*Myiarchus cinerascens*), and golden-crowned sparrow (*Zonotrichia atricapilla*).

On-site chaparral vegetation provides habitat for resident species such as the western scrub-jay, California thrasher, wren, Bewick's wren, California quail, Anna's hummingbird, northern mockingbird, California towhee, spotted towhee (*Pipilo erythrophthalmus*), bushtit (*Psaltriparus minimus*), black phoebe (*Sayornis nigricans*), and house finch (*Carpodacus mexicanus*). Migratory species which utilize chaparral communities include the white-crowned sparrow, golden-crowned sparrow, Costa's hummingbird, orange-crowned warbler (*Vermivora celata*), black-throated gray warbler (*Dendroica nigrescens*), Allen's hummingbird (*Selasphorus sasin*), black-chinned hummingbird (*Archilochus alexandri*), and fox sparrow (*Passerella iliaca*).

Grassland communities provide habitat for resident species such as the house finch. Grassland communities are also utilized by a number of migratory species including the horned lark (*Eremophila alpestris*), lark sparrow (*Chondestes grammacus*), western kingbird (*Tyrannus verticalis*), song sparrow, and Brewer's blackbird (*Euphagus cyanocephalus*). In addition, raptors often seen searching grassland areas for prey include the American kestrel (*Falco sparverius*), red-tailed hawk (*Buteo jamaicensis*), and turkey vulture (*Cathartes aura*).

The native woodland communities on-site, including coast live oak woodland and willow woodland, provide habitat for many bird species. Resident species observed include the following species: the northern flicker (*Colaptes auratus*), black phoebe, Anna's hummingbird, western scrub-jay, mourning dove (*Zenaidura macroura*), bushtit, acorn woodpecker (*Melanerpes formicivorus*), barn owl (*Tyto alba*), great horned owl (*Bubo virginianus*), oak titmouse (*Parus inornatus*), house wren (*Troglodytes aedon*), Hutton's vireo (*Vireo huttoni*), Cassin's vireo (*Vireo cassinii*), American goldfinch (*Carduelis tristis*), lesser goldfinch (*Carduelis psaltria*), American crow (*Corvus brachyrhynchos*), and common raven (*Corvus corax*).

Migratory species identified from on-site woodland communities include the black-chinned hummingbird, Costa's hummingbird, song sparrow, Nuttall's woodpecker (*Picoides nuttallii*), ash-throated flycatcher, western bluebird (*Sialia mexicana*), American robin (*Turdus migratorius*), yellow-rumped warbler (*Dendroica coronata*), Wilson's warbler (*Wilsonia pusilla*), yellow warbler (*Dendroica petechia brewsteri*), western tanager (*Piranga ludoviciana*), rufous-crowned sparrow (*Aimophila ruficeps*), white-crowned sparrow, Bullock's oriole (*Icterus galbula*), western kingbird, common yellowthroat (*Geothlypis trichas*), cliff swallow (*Hirundo pyrrhonota*), and western wood-pewee (*Contopus sordidulus*). The raptors most commonly observed on-site in oak woodland communities were the Cooper's hawk (*Accipiter cooperii*) and red-tailed hawk.

The eucalyptus grove provides habitat for several species, but is considered to have lower biological value than native woodland habitats. While eucalyptus does provide nectar, cover, nesting, and perching opportunities, the trees generally do not provide significant carbohydrate and protein resources. In addition, plants growing in the eucalyptus understory are primarily non-native grasses and forbs. Nevertheless, birds noted on-site utilizing eucalyptus include bullock's oriole, Anna's and Allen's hummingbird, Nuttall's woodpecker, northern flicker, European starling (*Sturnus vulgaris*), common raven, brown-headed cowbird (*Molothrus ater*), great horned owl, Cooper's hawk, and red-tailed hawk.

4.4 MAMMALS

Physical evidence rather than direct visual identification determined identification of mammals on the project site. Many of the mammal species, which could potentially occur on-site are nocturnal and would not have been active during the site visits. The diverse habitats on-site provide a multitude of services for mammal species, including use for foraging, nesting/burrowing, and wildlife movement.

The coastal sage scrub and alluvial scrub communities represent potential habitat for a number of mammals. Species identified on-site, either by direct observation or physical evidence, include the Audubon's cottontail (*Sylvilagus audubonii*), California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), deer mouse (*Peromyscus maniculatus*), desert woodrat (*Neotoma lepida*), coyote (*Canis latrans*), striped skunk (*Mephitis mephitis*), bobcat (*Lynx rufus*), and mule deer (*Odocoileus hemmionus*).

The chaparral communities on-site provide habitat for the Audubon's cottontail, brush rabbit (*Sylvilagus bachmani*), California ground squirrel, Pacific kangaroo rat (*Dipodomys agilis*), deer mouse, desert woodrat, coyote, gray fox (*Urocyon cinereoargenteus*), striped skunk, bobcat, and mule deer.

The grassland communities on-site provide potential habitat for the ornate shrew, Botta's pocket gopher, western harvest mouse (*Reithrodontomys megalotis*), deer mouse, California vole (*Microtus californicus*), coyote, striped skunk, and bobcat.

The riparian communities on-site, especially areas of Devil Canyon associated with permanent water sources can be heavily utilized. Therefore, the majority of mammals present on-site

would be expected to concentrate in riparian areas. Species which are known or have the potential to occur within the riparian communities on-site include deer mouse, California vole, California ground squirrel, Merriam's chipmunk (*Tamias merriami*), coyote, ringtail (*Bassariscus astutus*), raccoon (*Procyon lotor*), western spotted skunk (*Spilogale gracilis*), striped skunk, mountain lion (*Felis concolor*), bobcat, and mule deer.

The woodland communities present on the project site, including southern coast live oak woodland and walnut woodland, provide habitat for numerous mammal species. Mammals known to utilize the woodland communities present on-site include the deer mouse, desert woodrat, California ground squirrel, coyote, gray fox, raccoon, striped skunk, bobcat, and mule deer. Non-native woodland communities, such as eucalyptus support opportunist mammals such as opossum, striped skunk, and California ground squirrel.

4.5 WILDLIFE MOVEMENT CORRIDORS

Wildlife, including large mammals such as mule deer and coyote regularly utilize the property, especially the northern portion of the property (i.e., "Deer Lake Highlands"). As discussed previously, the site provides foraging and breeding habitat for a number of reptiles, amphibians, birds, and mammals. Wildlife movement corridors link together or connect areas of suitable natural habitat that is otherwise separated by rugged topography, human disturbance, or changes in vegetation. Disruption of these corridors and fragmentation of the natural areas, which they connect, lead to isolated patches or "islands" of wildlife habitat. According to Noss (1983) and Soule and Gilpin (1991), wildlife corridors are required by animals for three main reasons: (1) to allow the movement of animals between remaining natural areas thus replenishing populations and maintaining genetic diversity; (2) provide escape routes from fire, predators, and human disturbances; and (3) provide a travel route for animals to disperse, forage, and breed. In the absence of these corridors studies by biologists such as Soule (1987) indicate that the larger mammals, such as mountain lions, mule deer and bobcats, will not likely persist over time in these isolated "islands" because they prevent the entry of new individuals and the associated genetic exchange vital to the health and preservation of the population. Therefore, the purpose or function of a wildlife corridor is to facilitate the movement of animals between two or more patches of habitat (Soule, 1991).

Because of existing development south and west of the site, and impending development east of the site, the property does not represent an important wildlife movement corridor for land-

bound animals. While Browns Canyon is likely utilized to some extent for seasonal movement, the canyon flows into a concrete culvert south of the property, and enters an urbanized area. Devil Canyon remains relatively natural from its confluence with Browns Canyon to its headwaters northwest of the project site. However, an approximately 25-foot debris dam erected in 1971 blocked access through the middle part of the canyon. Some resident species, including birds, amphibians, and mammals such as Merriam's chipmunk, are locally common in Devil Canyon. However, sign of larger mammals is scarce. It is likely that Devil Canyon may have been more heavily utilized by larger species of wildlife in the past, before construction of the debris dam.

Regional wildlife movement studies have been prepared for The Nature Conservancy (TNC) and the Santa Monica Mountains Conservancy (SMMC) and include the vicinity of the project site (Edelman, 1990). This study identifies regionally important wildlife movement corridors in the vicinity of the project site. Most of these areas lie west of the project site, where the proximity of the Santa Susana Mountains to the Simi Hills may allow for movement between these areas. No on-site regionally important wildlife movement corridors were identified in these studies.

5.0 SENSITIVE BIOLOGICAL RESOURCES

5.1 SENSITIVE VEGETATION COMMUNITIES

Three vegetation communities located within the project site are considered sensitive by state, federal, or local resource protection agencies. These communities include coastal sage scrub, willow woodland, and coast live oak woodland. Oak woodland/willow woodland is considered sensitive due to the sensitivity status of willow woodland and coast live oak woodland.

5.1.1 COASTAL SAGE SCRUB/NON-NATIVE GRASSLAND

Coastal sage scrub is considered a sensitive vegetation type throughout much of Southern California, primarily in regions known to support the federally-listed threatened coastal California gnatcatcher. Coastal sage scrub has an S3.1 (between 10,000 and 50,000 extant acres and a high level of threat) ranking by the CDFG. Recent observations of the coastal California gnatcatcher in northern Los Angeles County could result in the application of higher levels of sensitivity to coastal sage scrub in regions where this habitat was not formerly considered sensitive. Approximately 2.39 acres of disturbed coastal sage scrub/non-native grassland ecotone has been identified onsite. This vegetation is located near the foundations of several abandoned structures that have burned to the ground. In this area, the coastal sage scrub is dominated by California sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), and deerweed (*Lotus scoparius*) with few other native species. The understory is dominated by non-native grasses and weedy herbs.

5.1.2 WILLOW WOODLAND

Willow woodland (i.e., Southern Mixed Riparian Forest) is ranked as S2.1 ("very threatened," with a small number of occurrences, individuals, or acres) by CDFG. The site supports approximately 9.88 acres of willow woodland in Devil Canyon. This type of habitat is known to support a wide diversity of wildlife, including several sensitive and/or listed wildlife species. The willow woodland has been invaded by the non-native giant reed (*Arundo donax*) in parts of lower Devil Canyon.

5.1.3 COAST LIVE OAK WOODLAND

Coast live oak woodland is not listed by CDFG as a sensitive vegetation type. However, the County of Los Angeles has identified this habitat as sensitive. At least one area in the northern portion of the project site has burned recently and is dominated by young trees. In general, the larger trees are associated with canyons and north-facing slopes. Oak woodlands support a variety of distinct plant and animal associates. In Devil Canyon, southern California black walnut occurs in the oak woodland.

In addition, a tree inventory was conducted by Poly and Associates and LNDG in 1998, February and December of 2000, respectively for coast live oaks (*Quercus agrifolia*). A total of 353 coast live oak trees over eight inches diameter at breast height (DBH) were identified on the site. One heritage tree was identified. The results of the tree inventory conducted by LNDG are provided in the *Oak Tree Report* dated December 20, 2000 and are discussed in Section 6.1.3.

5.2 SENSITIVE PLANT SPECIES

Focused surveys were conducted for special-status plant species with the potential to occur on the project site. Two special-status plant species were identified on the project site: Plummer's mariposa lily and southern California black walnut. In addition, coast live oak (*Quercus agrifolia*) have been identified on the project site which is subject to County of Los Angeles Oak Tree Ordinance (No. 93-0018). Table 5.1 summarizes the potential plant species found on the project site and its associated habitats. The status of the species are listed according to the CDFG Natural Diversity Database. Results of field work and surveys are also listed in the table.

Braunton's milkvetch (*Astragalus brauntonii*) is a short-lived, stout perennial in the pea family federally-listed as endangered and as a List 1B plant (plants that are rare or endangered) by the CNPS. This plant occurs below 1,500 feet elevation in coastal sage scrub and chaparral in Los Angeles, Orange, and Ventura counties. A population is known from the Oat Mountain quadrangle (CNPS, 1994). This species is often found on carbonate soils, primarily associated with recent burns or other disturbances such as grading. Typically, Braunton's milk-vetch will occupy a site for the first few years following a disturbance, and then will become less prevalent after a number of years. The species then persists in the soil seed bank

until the next disturbance or other event necessary to stimulate germination. This species is threatened by development and alteration of historic fire regimes. A wildfire passed through the southern end of the site within the past several years. This burned area and other disturbed areas on-site would be considered typical habitats for Braunton's milk-vetch if calcareous soils also existed on the site. Braunton's milk-vetch was not observed during plant surveys for the project site and is not likely to be present.

Nevin's barberry (*Berberis nevini*) is a federally- and state-listed endangered species and a CNPS List 1B plant. This species is a shrubby member of the barberry family. This shrub is 3 to 12 feet tall with dull blue-green pinnately compound leaves with leaflets that are both dentate and spinose. This woody shrub typically stems from rhizomes and produces flowers that are approximately ½ inch in diameter in the spring and early summer. Numerous berry-like fruits are produced in bunches ranging in color from yellow to red. This shrub occurs below 2,000 feet elevation in sandy areas in coastal sage scrub and chaparral in Los Angeles, San Bernardino, and Riverside counties. This species is threatened by development and road maintenance. Nevin's barberry was not observed on the project site and is not likely to be present.

Catalina mariposa lily (*Calochortus catalinae*) is a bulb-forming perennial in the lily family designated by CNPS as a List 4 (plant that has limited distribution – a watch list) plant. This species is endemic to California but is widespread, occurring in nine coastal California counties. Habitat includes chaparral, coastal sage scrub, woodland communities, and grasslands below 2,000 feet. Although potential habitat is present on-site, this species was not observed on the project site.

Slender mariposa lily (*Calochortus clavatus* var. *gracilis*) is a federal Species of Concern and a CNPS List 1B plant. This species is a bulb-forming perennial member of the lily family. This species is endemic to chaparral slopes below 4,000 feet along the south base of the San Gabriel Mountains and near Newhall, and is known from the vicinity of the project site. Although a similar species, *Calochortus clavatus* var. *pallidus* was identified on the project site, slender mariposa lily was not observed.

Plummer's mariposa lily (*Calochortus plummerae*) is a federal Species of Concern and a CNPS 1B species. This species is known from several vegetation communities and is found in Los Angeles, Ventura, Riverside, and San Bernardino counties. Plummer's mariposa lily occurs on the project site, in association with chamise chaparral vegetation. Plummer's mariposa lily is

Table 5.1
Sensitive Plant Species Potentially Occurring On-Site

Species	Status			Habitat	Observed?
	Federal	California	CNPS		
Braunton's milkvetch (<i>Astragalus brauntonii</i>)	Endangered	None	1B	Below 1,500 feet elevation in coastal sage scrub and chaparral; carbonate soils primarily associated with recent burns or other disturbances such as grading.	No
Nevin's barberry (<i>Berberis nevinii</i>)	Endangered	Endangered	1B	Below 2,000 feet elevation in sandy areas of coastal sage scrub and chaparral.	No
Catalina mariposa lily (<i>Calochortus catalinae</i>)	None	None	4	Endemic to California; chaparral, coastal sage scrub, woodland communities and grasslands below 2,000 feet.	No
Slender mariposa lily (<i>Calochortus clavatus</i> var. <i>gracilis</i>)	Species of Concern	None	1B	Endemic to chaparral slopes below 4,000 feet.	No
Plummer's mariposa lily (<i>Calochortus plummerae</i>)	Species of Concern	None	1B	Chamise chaparral.	Yes ^a
San Fernando Valley Spineflower (<i>Chorizanthe parryi</i> var. <i>fernandina</i>)	Proposed	Proposed	1B	Sandy openings in coastal sage scrub or non-native grassland.	No
Slender-horned spineflower (<i>Dodecahema leptoceras</i>)	Endangered	Endangered	1B	Washes and other sandy open habitats.	No
Santa Susana tarplant (<i>Hemizonia mintbornii</i>)	Species of Concern	Rare	1B	Rocky openings in chaparral.	No ^b
Southern California black walnut (<i>Juglans californica</i> var. <i>californica</i>)	None	None	4	Cismontane southern California.	Yes ^c
Robinson's pepper grass (<i>Lepidium virginicum</i> var. <i>robinsonii</i>)	None	None	1B	Coastal sage scrub and chaparral.	No
Ocellated Humboldt lily (<i>Lilium humboldtii</i> ssp. <i>ocellatum</i>)	Species of Concern	None	4	Canyons below 3,000 feet.	No
Fish's milkwort (<i>Polygala cornuta</i> var. <i>fishiae</i>)	None	None	4	Shaded, rocky places in canyons below 3,000 feet.	No
Coast live oak (<i>Quercus agrifolia</i>)	Listed as "sensitive" by the County of Los Angeles			Dominant species in coast live oak woodland, but does occur in other plant communities.	Yes ^d

^a 1,793 individuals identified on-site in 61.04 acres.

^b Was observed off-site on a road cut near Topanga Canyon Boulevard and 118 Freeway.

^c Scattered individuals in Devil Canyon.

^d 353 oak trees were evaluated on-site and one (1) heritage oak tree was identified.

Source: Glenn Lukos Associates, Inc., 2000; L. Newman Design Group, Inc., 2000.

supported by soils derived from sandstone bedrock (Gaviota Sandy Loams), with less dense patches occurring on soils derived from granitic material. Plummer's mariposa lily is absent from very dense or north-facing stands of chaparral, and from dense stands of vegetation. This species is distributed at an approximate density of 20 to 30 plants per acre throughout the northern portion of the site, with two dense subpopulations totaling approximately one acre and supporting approximately 350 plants located in the north-central section of the site [Exhibit 5]. Field work was conducted during the spring following the heavy 1997-1998 El Niño event, thus the detectability of this species was very high and 1,793 individual Plummer's mariposa lily plants were identified on the project site.

San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*) is a federal Species of Concern and a CNPS 1A (plant that is presumed extinct in California) species. This species is a diminutive annual in the buckwheat family, was formerly assumed to be extinct. This plant was rediscovered in Calabasas during the spring of 1999 by botanists of GLA. This species was known from sandy areas in several southern California localities, including Chatsworth Reservoir. Although two related plants were identified, Turkish rugging (*Chorizanthe staticoides*) and lastarriaea (*Lastarriaea coriacea*), during general botanical surveys in 1998 and focused surveys in 1999-2000, the previously identified populations of San Fernando Valley spineflower could not be located at the Chatsworth Reservoir during 1999 and is not likely to be present on the project site.

Slender-horned spineflower (*Dodecabeema leptoceras*) is a federally- and state-listed endangered species and a CNPS List 1B plant. This species is a low-growing annual herb in the buckwheat family, with a spread from one to four inches above vernal, basal leaves. The flowers are white to pink and approximately one to two millimeters in length and flowering occurs in the late spring and early summer months. This species is known from Los Angeles, Riverside, and San Bernardino counties, in washes and other sandy, open habitats at elevations between 600 and 2,100 feet. This plant is threatened by development, vehicles, and loss of historical flooding regimes. Slender-horned spineflower was not observed on the project site and is not likely to be present.

Santa Susana tarplant (*Hemizonia minthornii*) is a federal Species of Concern and a CNPS List 1B plant. Santa Susana tarplant is known from rocky openings in chaparral in the vicinity of Santa Susana pass and in the Santa Monica Mountains. A roadcut near Topanga Canyon Boulevard and the 118 Freeway (approximately 0.2 mile from the project site) may have supported this species. Potential habitat including rock outcrops and openings in scrub

are present on-site, however, non-native fountain grass (*Pennisetum setaceum*) dominates the cut slope. Non-native fountain grass is an aggressive weed that would likely prevent Santa Susana tarplant from establishing. In addition, evidence of clearing would likely prevent Santa Susana tarplant from establishing on the cut slope. Santa Susana tarplant was not observed on the project site.

Southern California black walnut (*Juglans californica* var. *californica*) is listed as a CNPS List 4. This species occurs throughout cismontane Southern California, but is declining in much of its range. Scattered individuals of Southern California black walnut have been identified on the site in Devil Canyon.

Robinson's pepper grass (*Lepidium virginicum* var. *robinsonii*) is an annual plant in the mustard family designated as a CNPS List 1B plant. This species occurs in coastal sage scrub and chaparral from Los Angeles County to Baja California. Robinson's pepper grass was not observed on the project site.

Ocellated Humboldt lily (*Lilium humboldtii* ssp. *ocellatum*) is a federal Species of Concern and a CNPS List 4 plant. This robust perennial herb is in the lily family. This species is known from several southern California counties, normally found in canyons below 3,000 feet. Ocellated Humboldt lily was not observed on the project site and is not likely to be present.

Fish's milkwort (*Polygala cornuta* var. *fishiae*) is a CNPS List 4 plant. This shrubby perennial is in the milkwort family. This species is found throughout southern California and Baja California in shaded, rocky places in canyons below 3,000 feet. Fish's milkwort was not observed on the project site and is not likely to be present.

Coast live oaks (*Quercus agrifolia*) are designated as "sensitive" by the County of Los Angeles. Coast live oak trees are native to southern California and are large evergreen trees with a broad round shape and large limbs. These trees are typically 30 to 70 feet tall with a broad spread between 35 to 80 feet wide. The leaves are glossy green and one to three inches long with a spiny round holly-like shape. The leaves are also distinctively cupped or curled at the edges. A total of 353 oak trees over eight inches diameter at breast height (DBH) were surveyed on the project site.

5.3 SENSITIVE WILDLIFE SPECIES

Focused surveys were conducted for special-status wildlife species with the potential to occur on the project site. Three special-status wildlife species were identified on the project site: Cooper's hawk, ashy rufous-crowned sparrow, and western yellow warbler. Table 5.2 summarizes the potential wildlife species found on the project site and its associated habitats. The status for each species is listed according to the CDFG Natural Diversity Database. Results of field work and surveys are also listed in the table.

Ringtail (*Bassariscus astutus*) is a California fully-protected species. This mammal is widespread through many habitats in California and the western North America. This species is non-migratory and is generally found within 1 km of permanent water. Because the site exhibits only seasonal water in Browns Canyon and Devil Canyon, there is a low probability that this species is resident on the site. As such, focused surveys were not conducted for this species.

California red-legged frog (*Rana aurora draytonii*) is a federally-listed threatened species. This species is a relatively large aquatic frog found from Humboldt, Shasta, and Trinity counties along the western third of the state to the Mexican border, and along the western slope of the Sierra Nevada range south to Mariposa County. The frog is rare in southern California, but has been recently identified in the Los Virgines Creek watershed, approximately six miles south of the project site. Surveys conducted in Browns and Devil Canyons in 1999 resulted in no observations of California red-legged frog. A letter from Peter H. Bloom to Brad Henderson of GLA dated October 7, 1999 documents the results of the red-legged frog surveys (see Appendix B), which were updated by Brad Henderson and Jeff Ahrens in spring of 2000.

Arroyo Southwestern Toad (*Bufo microscaphus californicus*) is a federally-listed endangered species and a California species of special concern. It is typically associated with higher order streams with sand and gravel bars and with slow moving water and shallow pools. Gravel bottoms for the shallow ponds are preferred for breeding. GLA biologists conducted a habitat assessment for this species and determined that suitable habitat for this species was not present on the site. As such, focused surveys were not conducted for this species.

San Diego horned lizard (*Phrynosoma coronatum blainvillei*) is a state Species of Concern. The site does provide potential habitat, including the favored food source for the San Diego

Coast horned lizard, harvester ants (*Pogonomyrmex* spp.) and suitable sandy soils. However, the San Diego Coast horned lizard was not observed on the project site.

Table 5.2
Sensitive Wildlife Species Potentially Occurring On-Site

Species	Status		Habitat	Observed?
	Federal	California		
Ringtail (<i>Bassariscus astutus</i>)	None	Fully Protected	Riparian areas and adjacent shrublands or forests	No (suitable habitat lacking)
California red-legged frog (<i>Rana aurora draytonii</i>)	Threatened	None	Riparian areas – aquatic species.	No ^a
Arroyo Southwestern Toad (<i>Bufo microscaphus californicus</i>)	Endangered	Species of Concern	Riparian and alluvial scrub	No (suitable habitat lacking)
San Diego horned lizard (<i>Phrynosoma coronatum blainvillei</i>)	None	Species of Concern	Sandy soils.	No
Two-striped garter snake (<i>Thamnophis hammondi</i>)	None	Species of Concern	Riparian areas – aquatic species.	No
Cooper's hawk (<i>Accipiter cooperii</i>)	None	Species of Concern	Woodland habitat.	Yes ^b
Ashy-rufous crowned sparrow (<i>Aimophila ruficeps canescens</i>)	None	Species of Concern	Coastal sage scrub and other xeric habitats; chaparral.	Yes ^c
Western yellow warbler (<i>Dendroica petechia brewsteri</i>)	None	Species of Concern	Migratory songbird nesting in riparian habitats.	Yes ^d
Southwestern willow flycatcher (<i>Empidonax traillii extimus</i>)	Endangered	Endangered ^e	Migratory songbird found in riparian habitats.	No
Coastal California gnatcatcher (<i>Polioptila californica californica</i>)	Threatened	None	Cismontane; coastal sage scrub.	No
Least Bell's vireo (<i>Vireo billi pusillus</i>)	Endangered	Endangered	Migratory songbird found in riparian habitats; willow thickets along streams.	No

^a Identified approximately six miles south of site.

^b Fledglings were also commonly observed in lower Devil Canyon

^c At least 3 to 4 pairs identified near Devil Canyon; No nesting confirmed but an increase in birds was observed, thus indicating nesting does occur.

^d Observed sporadically during spring and fall migration; possible nesting on-site although none observed.

^e Entire species endangered.

Source: Glenn Lukos Associates, Inc., 2000.

Two-Striped Garter Snake (*Thamnophis hammondi*) is a state Species of Concern and a highly aquatic snake known from Monterey County to northwestern Baja California. The species is relatively common in coastal southern California, but has declined from modification of stream courses, urban development, and introduction of introduced predators. Although suitable habitat is present in the study area in Devil Canyon and Browns Canyon, this species was not observed on the project site.

Cooper's hawk (*Accipiter cooperii*) is a state Species of Concern and are found in woodland habitats. They prey primarily on birds but they are known to eat small mammals, reptiles, amphibians, insects and fish. Cooper's hawks was observed throughout the 1998 and 2000 field seasons. Fledglings were commonly observed in lower Devil Canyon during field work in 2000.

Ashy rufous-crowned sparrow (*Aimophila ruficeps canescens*) is a state Species of Concern and a year-round resident of Southern California. This species is frequently found in coastal sage scrub and in other xeric habitats. Like other sparrows, the ashy rufous-crowned sparrow primarily eats seeds and insects. At least three to four pairs of ashy rufous-crowned sparrows were identified on the site, primarily near Devil Canyon in 1998, and 2000, with a single observation in the Deer Lake Highlands portion of the site in 1999. No nesting pairs of ashy-rufous crowned sparrow were confirmed on the site during 1998, 1999, or 2000, but since the birds have been seen in multiple years, it is assumed that some nesting occurs on the site.

Western yellow warbler (*Dendroica petechia brewsteri*) is a state Species of Special Concern and a migratory songbird nesting in riparian habitats. This species was observed sporadically during Spring and Fall migration. Although there is potential for this species to nest on the project site, nesting activity was not observed.

Southwestern willow flycatcher (*Empidonax traillii extimus*) is a federally- and state-listed endangered small, migratory songbird also found in riparian habitats. The southwestern willow flycatcher breeds from the south end of the Sierra Nevada Range south to Baja California and east to western Texas. The species has been depleted due to the loss and adverse modification of riparian habitat, and is threatened by brown-headed cowbird nest parasitism. Wintering habitat is not well known, but is thought to extend from Mexico south at least to Panama. Protocol surveys conducted in 1998 did not result in observations of southwestern willow flycatcher. Focused surveys for this species were repeated in 2000, however the species was not observed. Reports from Kurt Campbell of Campbell

BioConsulting dated July 24, and September 26, 2000 documents the results of the 2000 protocol surveys (Appendix B).

Coastal California gnatcatcher (*Polioptila californica californica*) is a federally-listed threatened species and occurs in many areas of cismontane Southern California from Ventura County to San Diego County. These birds are not common in the vicinity of the project site but have been identified in Simi Valley/Moorpark and in the Sylmar area. In 1998, GLA conducted surveys for the coastal California gnatcatcher according to the guidelines issued by the USFWS (1997). During the surveys, which covered all areas of coastal sage scrub and coastal sage scrub ecotone, no coastal California gnatcatchers were observed on the site. A letter report to Kirk Waln of the USFWS dated June 4, 1998 documents the findings of the surveys (Appendix B). The gnatcatcher surveys were repeated in 2000, and a letter report to the USFWS dated August 3, 2000 documents the results of the 2000 protocol coastal California gnatcatcher surveys (Appendix B). The coastal California gnatcatcher has not been observed on the site during protocol surveys or at any other time. In addition, during subsequent field surveys, it was determined that no suitable gnatcatcher habitat exists on the additional 13 acres. No further surveys are required for the coastal California gnatcatcher.

Least Bell's vireo (*Vireo billi pusillus*) is a federally- and state-listed endangered small, migratory songbird found in riparian habitats. The least Bell's vireo was once common throughout the Central Valley extending to Baja California. The species has been depleted due to loss of riparian habitat and the increase in brown-headed cowbird nest parasitism. Least Bell's vireo is often found in willow thickets along streams, breeding in southern California and wintering in Mexico. Protocol surveys conducted in 1998 did not result in observations of least Bell's vireo. A letter report to Kirk Waln of the USFWS dated August 24, 1998 documents the results of the 1998 vireo surveys (Appendix B). Focused surveys for this species were repeated in the spring/summer of 2000. A letter report to Richard Garlinghouse of Chatsworth Presidio Partners LLC dated September 21, 2000 documents the results of the protocol surveys (Appendix B).

5.4 JURISDICTIONAL RESOURCES

The Chatsworth Ridge Estates project contains one blue-line drainage as depicted on USGS topographic map [see Exhibit 2]. On March 18, 19, 23, 26, April 6, May 29, June 1, and June 3, 1998, and December 2000, regulatory specialists of GLA examined the project site to

determine the limits of (1) Corps jurisdiction pursuant to Section 404 of the Clean Water Act, and (2) CDFG jurisdiction pursuant to Division 2, Chapter 6, Section 1603 of the Fish and Game Code. A letter report dated July 27, 1998) documenting these findings was prepared and submitted to the client. Jurisdictional areas are depicted on Exhibit 4.

As shown in Table 5.3, Corps jurisdiction at the site, including portions of Devil Canyon totals approximately 65,075 square feet (1.49 acres), of which approximately 40,200 square feet (0.92 acre) consist of jurisdictional wetlands. CDFG jurisdiction, includes everything within Corps jurisdiction, extending beyond Corps jurisdiction to the limits of the riparian canopy. CDFG jurisdiction at the site totals approximately 400,325 square feet (9.19 acres) of which approximately 383,015 square feet (8.79 acres) consisting of vegetated riparian habitat (see Table 5.3).

5.4.1 DRAINAGE/CANYON LOCATIONS

Drainage 1

Corps jurisdiction associated with Drainage 1 totals approximately 1,150 square feet (0.03 acre) and is limited to the ordinary high water mark (OHWM) of the channel. CDFG jurisdiction associated with Drainage 1 totals approximately 28,500 square feet (0.65 acre), all of which constitutes riparian vegetation. The drainage supports coast live oak (*Quercus agrifolia*) and western sycamore (*Platanus racemosa*). Drainage 1 is located in a moderately steep part of the site and varies from one to two feet in width. Drainage 1 consists of an incised channel with a sandy bottom at the upper reach and contains some steep areas on sandstone bedrock near the edge of the property. No wetlands are associated with Drainage 1.

Drainage 2

Corps jurisdiction associated with Drainage 2 and its tributaries totals approximately 3,670 square feet (0.084 acre) and is limited to the OHWM of the channel. CDFG jurisdiction associated with Drainage 2 and its tributaries totals approximately 5,770 square feet (0.13 acre) and includes 2,240 square feet (0.051 acre) of riparian vegetation. Drainage 2 and its tributaries extend from the first discernible OHWM to where it leaves the property. Drainage 2 varies from one to three feet in width, and consists of an incised channel with a rocky bottom. Areas adjacent to the drainage are vegetated with upland chaparral shrubs such as chamise

(*Adenostoma fasciculatum*), black sage (*Salvia mellifera*), laurel sumac (*Malosma laurina*), hoary leaf ceanothus (*Ceanothus crassifolius*), toyon (*Heteromeles arbutifolia*), and other upland species. An 80-foot section in the upper reach of Drainage 2 supports coast live oak. No wetlands are associated with Drainage 2 or its tributaries.

Drainage 3

Corps jurisdiction associated with Drainage 3 and its tributaries is limited to the OHWM of the channels and totals approximately 4,355 square feet (0.10 acre). CDFG jurisdiction associated with Drainage 3 and its tributaries totals approximately 5,325 square feet (0.12 acre) and includes 1,290 square feet (0.03 acre) of riparian habitat. Drainage 3 varies in width from one to three feet. Drainage 3 is steep and rocky in places, but along the middle and upper reaches there are areas of little topographic relief. The channel bottom in Drainage 3 ranges from sandstone bedrock to areas of cobbles, sand, or soil. The channel flows through areas vegetated with upland chaparral shrubs, herbs, and grasses. There are no wetlands associated with Drainage 3 or its tributaries.

Drainage 4

Corps jurisdiction associated with Drainage 4 and its tributaries totals 12,130 square feet (0.28 acre) and is limited to the OHWM of the channels. CDFG jurisdiction associated with Drainage 4 and its tributaries totals 66,530 square feet (1.53 acres) and includes 59,475 square feet (1.36 acres) of riparian vegetation. Drainage 4 varies from one to three feet in width and the incised channel bottom consists of bedrock or sand. Drainage 4 flows through areas vegetated with chaparral and supports coast live oak in the lower reach. There are no wetlands associated with Drainage 4 or its tributaries.

Drainage 5

Corps jurisdiction associated with Drainage 5 totals approximately 1,505 square feet (0.034 acre) and is limited to the OHWM of the channel. CDFG jurisdiction associated with Drainage 5 totals approximately 6,265 (0.14 acre) and includes 5,640 square feet (0.13 acre) of riparian vegetation. This drainage is located near the southeast corner of the site where it meets Browns Canyon. The channel bottom is incised with a rocky or sandy bottom and ranges from one to three feet wide. The upper 560-foot reach of Drainage 5 flows through areas dominated by typical chaparral vegetation and is considered ephemeral. The lower reach

of Drainage 5 supports coast live oak woodland mixed with willow woodland. Typical species include poison oak (*Toxicodendron diversilobum*), mugwort (*Artemisia douglasiana*), coast live oak, and southern California black walnut (*Juglans californica* var. *californica*). There are no wetlands associated with drainage 5.

Table 5.3
Drainages Located on the Project Site

Location	Jurisdiction

Source: Glenn Lukos Associates, Inc., 2000.

Drainage 6

Drainage 6 is located off site.

Drainage 7

Corps jurisdiction associated with Drainage 7 and its tributary totals approximately 985 square feet (0.023 acre). CDFG jurisdiction associated with Drainage 7 and its tributary totals approximately 985 square feet (0.023 acre). Drainage 7 is located in the northwest area of the property, and meets Browns Canyon near a flat area vegetated with oaks. The OHWM of Drainage 7 averages one to two feet in width. The channel banks are vegetated with typical chaparral species. The drainage bottom ranges from bedrock to sand and includes a vertical drop over a bedrock ledge. There are no wetlands associated with Drainage 7 or its tributaries.

Drainage 8

Drainage 8 is located off site.

Drainage 9

Corps jurisdiction associated with Drainage 9 and its tributary totals approximately 1,560 square feet (0.036 acre) and is located north of Devil Canyon, and south of Drainage 4. CDFG jurisdiction associated with Drainage 9 totals approximately 1,560 square feet (0.036 acre). No riparian vegetation is associated with Drainage 9. This channel averages one to two feet in width, and the bottom consists of rocks or sandstone bedrock. The channel flows through areas dominated by chaparral. There are no wetlands associated with Drainage 9 or its tributary.

Drainage 10

Corps jurisdiction associated with Drainage 10 and its tributary totals approximately 760 square feet (0.02 acre) and is limited to the ordinary high water mark (OHWM) of the channel. CDFG jurisdiction associated with Drainage 10 totals approximately 1,340 square feet (0.03 acre) and includes 1,200 square feet (0.03 acre) of riparian vegetation. The drainage supports mule fat (*Baccharis salicifolia*). Drainage 10 is located in the western portion of the 13-acre addition to the site and varies from two to four feet in width. Drainage 10 consists of an incised channel with a sandy or bedrock bottom. No wetlands are associated with Drainage 10.

Devil Canyon

Corps jurisdiction associated with Devil Canyon totals approximately 106,755 square feet (2.45 acres). CDFG jurisdiction associated with Devil Canyon totals approximately 467,900 square feet (10.74 acres) and includes 463,275 square feet (10.63 acres) of riparian vegetation. This blue-line drainage flows into Browns Canyon east of the site. The width of the channel varies from 8 to 15 feet, and the bottom consists of sand and silt. Vegetation associated with Devil Canyon consists of a mosaic of willow woodland, and coast live oak woodland. Typical component species supported by this drainage include arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), narrow-leaved willow (*Salix exigua*), western sycamore (*Platanus racemosa*), Fremont cottonwood (*Populus fremontii*), black cottonwood (*Populus balsamifera*

ssp. *trichocarpa*), giant reed (*Arundo donax*), coast live oak (*Quercus agrifolia*), mugwort (*Artemisia douglasiana*), poison oak (*Toxicodendron diversilobum*), and California blackberry (*Rubus ursinus*).

5.4.2 REGULATORY REQUIREMENTS

Impacts to certain habitats and species associated with the project site are regulated by federal, state, and local agencies, including the Corps, CDFG as well as the County of Los Angeles pursuant to CEQA.

U.S. Army Corps of Engineers

Pursuant to Section 404 of the Clean Water Act, the Corps regulates the discharge of dredged and/or fill material into waters of the United States. The term "waters of the United States" is defined at 33 CFR Part 328 and includes (1) all navigable waters (including all waters subject to the ebb and flow of the tide), (2) all interstate waters and wetlands, (3) all other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation or destruction of which could affect interstate or foreign commerce, (4) all impoundments of waters mentioned above, (5) all tributaries to waters mentioned above, (6) the territorial seas, and (7) all wetlands adjacent to waters mentioned above. Wetlands are defined at 33 CFR 328.3(b) as "those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support...a prevalence of vegetation typically adapted for life in saturated soil conditions."

Issuance of a Section 404 Permit to discharge dredged or fill material into jurisdictional waters is considered a federal action and cannot be undertaken by the Corps if the permitted actions could adversely affect federal-listed (or proposed) endangered or threatened species. Where listed or proposed species could be adversely impacted by a permitted action, the Corps must consult with USFWS prior to issuing a section 404 permit.

California Department of Fish and Game

Pursuant to Division 3, Chapter 1.5, Sections 2050-2116 of the California Fish and Game Code, the CDFG prohibits take of state-listed species. If state-listed species are impacted by

project implementation, a California Endangered Species Act (CESA) permit would be required. Likewise, take of plants listed as rare under the California Native Plant Protection Act (CNPPA) are subject to CDFG approval. Impacts to state-listed species must be fully mitigated in order to satisfy CESA and CNPPA requirements.

Pursuant to Division 2, Chapter 6, Sections 1600-1603 of the California Fish and Game Code, the CDFG regulates all diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake supporting fish or wildlife. CDFG defines a "stream" (including creeks and rivers) as "a body of water that flows at least periodically or intermittently through a bed or channel having banks and supports fish or other aquatic life. This includes watercourses having surface or subsurface flow that supports or has supported riparian vegetation."

CDFG jurisdictional limits for rivers, streams, and lakes closely mirror those of the Corps. Exceptions are CDFG's exclusion of isolated wetlands (those not associated with a river, stream, or lake), the addition of artificial stock ponds and irrigation ditches constructed on uplands, and the addition of riparian habitat supported by a river, stream, or lake regardless of the riparian area's federal wetland status.

County of Los Angeles

Oak trees within the County of Los Angeles are protected by law. County Ordinances #88-0157, #93-0017, and #99-0018 makes the cutting, moving, removal, or encroachment into the protected zone of an oak tree without a permit a misdemeanor. The protected zone will mean that area within the dripline of an oak tree and extending there from to a point at least five feet outside the dripline, or 15 feet from the trunk(s) of a tree, whichever distance is greater.

The major thrust of the Oak Tree Policy (OTP) was established to recognize oak trees as significant, historical, aesthetic and valuable ecological resources, and as one of the most picturesque trees in Los Angeles County. In addition, the OTP intends to create favorable conditions for the preservation and propagation of this unique, threatened plant heritage, particularly those trees, which may be classified as "heritage oak trees". It is the intent of the OTP to maintain and enhance the general health, safety, and welfare by assisting in counteracting air pollution, and in minimizing soil erosion and other related environmental damages.

6.0 IMPACTS TO BIOLOGICAL RESOURCES

Impacts to biological resources were evaluated with respect to special status plant and wildlife species including associated habitats and streambeds/wetlands and their associated vegetation. Direct impacts involve the initial loss of habitats by grading and construction. Indirect impacts are related to disturbance from construction, such as dust and noise, or from activities of future residents.

6.1 SENSITIVE VEGETATION COMMUNITIES

Project impacts were calculated by Forma Systems, Inc., using a Geographic Information System (GIS) file of the existing biological resources superimposed on the Tentative Tract Map dated October 6, 2000. Fuel modification impacts were calculated from the GIS fuel modification file prepared by LNDG. The County of Los Angeles requires fuel modification for developed areas in the urban/wildland interface. In native tree-dominated vegetation communities, the lower branches of trees may be pruned, but trees would be left standing. Impacts to other vegetation communities are assumed to be total and permanent. Therefore, fuel modification impacts to tree-dominated communities will be assumed to be partial impacts.

The areas of impact and subsequent analysis presented herein apply only to the proposed plan and no other variants or alternatives. A total of 176.44 acres (153.90 acres of permanent impact and 22.53 acres of partial fuel modification impact) of on-site biological resources would be impacted by project implementation as summarized in Table 6.1 and discussed below. These impacts include all anticipated disturbance to the ground. The impacts may be permanent or temporary and include mass grading, remedial grading, road construction, fuel modification, and utility easements. Modifications to the grading plans described above may require revision of the analysis and conclusions presented in this report.

6.1.1 CHAMISE CHAPARRAL

Implementation of the proposed project would result in the loss of 137.68 acres of chamise chaparral due to grading activities and 20.73 for fuel modification. Chamise chaparral is

abundant in Los Angeles County with thousands of acres protected by Angeles National Forest. Chamise chaparral is not listed as a Rare Natural Community by CDFG. The loss of a total of 158.41 acres of chamise chaparral would not be significant.

Table 6.1
Vegetation Impact Summary

Vegetation Association	Total Acres	Grading Impacts (permanent)	Fuel Modification Impacts (partial)	Total Acres Impacted (permanent/partial)
Chamise Chaparral	195.72	125.62	20.73	146.35
Coastal Sage Scrub/Non-Native Grassland	2.39	2.39	0.00	2.39
Coast Live Oak Woodland	5.73	0.68	0.62	1.30
Willow Woodland	9.88	0.02	0.01	0.03
Oak Woodland/Willow Woodland	0.58	0.00	0.00	0.00
Non-Native Grassland ^a	7.56	2.53	0.58	3.11
Eucalyptus Grove	0.18	0.01	0.00	0.01
Previously Graded or Developed	13.53	10.59	0.60	11.19
Total	235.58	141.84	22.54	164.38

^a Includes some developed areas

Source: Glenn Lukos Associates, Inc., 2000.

6.1.2 COASTAL SAGE SCRUB/NON-NATIVE GRASSLAND

Implementation of the proposed project would result in the loss of 2.39 acres of coastal sage scrub due to grading activities. No loss to coastal sage scrub would result from fuel modification impacts. This vegetation covers a disturbed site previously occupied by homes, is small in size, lacks diversity, and does not support the coastal California gnatcatchers. Impacts to this area of coastal sage scrub vegetation would not be significant.

6.1.3 COAST LIVE OAK WOODLAND

Implementation of the proposed project would result in the loss of 0.68 acre of coast live oak woodland due to grading activities and fuel modification would disturb an additional 0.62

acres of oak understory but would not affect mature trees. Currently, there is a total of 353 oak trees (all of which are of the species *Quercus agrifolia*) and one heritage tree on the project site. Of this total, 65 oak trees would require removal in order to construct this project. None of the oak trees proposed for removal are of heritage status. Fuel modification would result in the removal of understory species, but would not result in the removal of oak trees. A detailed list of the inventory can be found in the report prepared by LNDG entitled *Oak Tree Survey Report* dated December 20, 2000. This habitat is considered as sensitive by the County of Los Angeles. Therefore, any loss of coast live oak woodland would be considered significant. However, with implementation of mitigation measures, impacts would be reduced to less than significant.

6.1.4 WILLOW WOODLAND

Implementation of the proposed project would result in impacts to 0.02 acres of willow woodland due to grading activities and 0.01 acre for fuel modification. An additional 0.30 acre of willow woodland was evaluated for impacts potentially resulting from two free-span bridge crossings of Devil Canyon and due to the height of the bridges, it was determined that shading would not be a measurable impact. All willow woodland on the site is under the jurisdiction of CDFG, and would be mitigated by habitat enhancement and/or replacement pursuant to Section 1603 of the California Fish and Game Code. Because the willow woodlands are under the jurisdiction of CDFG; and the habitat is considered sensitive in southern California, any impacts are potentially significant. With the mitigation measures for Corps and CDFG jurisdiction discussed in Section 6.1.1, direct impacts to 0.03 acre of willow woodland would be less than significant.

6.1.5 OAK WOODLAND/WILLOW WOODLAND

Implementation of the proposed project would not result in impacts from grading activities or regarding fuel modification to oak woodland/willow woodland on the project site.

6.1.6 NON-NATIVE/PREVIOUSLY DISTURBED

Implementation of the proposed project would result in impacts to 2.53 acres of non-native grassland due to grading activities and 0.58 acre for fuel modification. Non-native grassland is dominated by non-native annual species and is widespread throughout southern California, and therefore, impacts to non-native annual grassland would not be significant.

Implementation of the proposed project would result in the loss of approximately 0.01 acre of eucalyptus due to grading activities. Eucalyptus is generally considered to be an undesirable and dangerous vegetation association in southern California. Blue gum is a destructive wildland weed, as listed by the California Exotic Pest Plant Council (CalEPPC List A-1). Red gum is afflicted by the red gum lerp psyllid (*Glycaspis brimblecombei*), a new exotic pest that has severely affected red gum trees on the project site. Both species of eucalyptus are afflicted with the longhorn boring beetle (*Phoracantha semipunctata*), a pest that tunnels through the trunks of trees, further stressing and weakening them. Eucalyptus would be removed from the project site to enhance the biological values of open space areas, reduce the risk of a canopy fire, and prevent further encroachment of eucalyptus into native habitats. The removal of eucalyptus grove would be a beneficial impact and less than significant.

Implementation of the proposed project would result in impacts to approximately 10.59 acres of previously developed areas due to grading activities and 0.60 for fuel modification. These areas currently provide little habitat for native species. Impacts to 11.19 acres of previously graded/developed areas would be less than significant.

6.2 GENERAL WILDLIFE & WILDLIFE MOVEMENT CORRIDORS

Many common animals, especially ground-nesting mammals and reptiles would be adversely affected by direct take and/or habitat loss associated with the implementation of the project. Under the proposed plan approximately 129.21 acres would remain open space, of which approximately 70.72 acres would be left undisturbed (i.e., existing conditions would not be impacted by grading or fuel modification), including riparian habitats associated with Devil Canyon. Large areas of chaparral are common to the north and west of the site and would continue to provide habitat for a variety of wildlife species. While it is acknowledged that the project would result in the loss of access to local foraging, cover, and water resources, wildlife

would likely continue to utilize open space portions of the site via Browns Canyon, upper Devil Canyon, and open space to the north. Therefore, the project would not have a significant effect on regional wildlife movement; and impacts on local wildlife populations would not be considered significant.

6.3 SENSITIVE PLANTS

The following sensitive plant species were not observed on the project site: Braunton's milkvetch, Nevin's barberry, Catalina mariposa lily, slender mariposa lily, San Fernando Valley spineflower, slender-horned spineflower, Santa Susana tarplant, Robinson's pepper grass, ocellated Humboldt lily, and Fish's milkwort. Therefore, no significant impacts would occur.

Plummer's mariposa lily was observed on the project site. Implementation of the project would result in direct impacts to approximately 61.02 acres of Plummer's mariposa lily habitat and up to 1,793 individuals identified on the site [Exhibit 5]. This species is endemic to southern California, but is found in fairly widespread habitats, including coastal sage scrub, chaparral, cismontane woodland, lower coniferous forests, and grasslands in Los Angeles, Ventura, Riverside, and San Bernardino counties. Because this species is listed on CNPS List 1B, impacts to an estimated 1,700 Plummer's mariposa lily individuals are considered significant.

Plummer's mariposa lily is present in low densities over large portions of the site. The large size of the Plummer's mariposa lily occurrence over a large portion of the site would be impossible to avoid. With the implementation of mitigation, the impacts are considered adverse due to the loss habitat quality and extent, but below a level of significance.

Southern California black walnuts were also identified scattered on the project site in Devil Canyon. However, implementation of the proposed project would not result in the removal of southern California black walnuts trees. No impacts to this species would be associated with project implementation.

6.4 SENSITIVE WILDLIFE

Implementation of the proposed project would not result in an impact to any state or federally listed wildlife species. The following sensitive wildlife species were not observed on the project site during protocol surveys: California red-legged frog, San Diego horned lizard, two-striped garter snake, southwestern willow flycatcher, coastal California gnatcatcher, and least Bell's vireo. Therefore, no significant impacts would occur.

Cooper's hawks were observed throughout the 1998 and 2000 field seasons and fledglings were commonly observed in lower Devil Canyon during field work in 2000. If construction should occur during the breeding season for migratory birds and/or raptors, there is a potential for impacts to an active nest. The loss of an active nest of a migratory bird protected pursuant to the Migratory Bird Treaty Act of 1918. The loss of a Cooper's hawk, or a common raptor species would be considered a potential violation of California Fish and Game Code Section 3513, 3503, and 3505.5 and would be considered as a significant impact. However, with avoidance of active nests under the direction of a qualified biologist, the impact would be reduced to less than significant.

Ashy rufous-crowned sparrows were observed in several locations on the site. This species is strongly associated with coastal sage scrub, grassland, and chaparral. Approximately 153.91 acres of associated habitat would be impacted resulting in impacts to an estimated one to two pairs of rufous-crowned sparrows. However, these pairs of rufous-crowned sparrows would likely be displaced to the open space areas north of the site. Thus, impacts would be considered adverse, but less than significant.

Western yellow warblers were observed sporadically during spring and fall migration. Although there is potential for this species to nest on the project site, nesting activity was not observed. Nearly all the willow woodland on the site will be preserved in perpetuity, thus the western yellow warbler will not be impacted by implementation of the project.

6.5 JURISDICTIONAL RESOURCES

Approximately 132,870 square feet (3.05 acres) of Corps jurisdiction was identified on the site. Construction of the project would impact approximately 18,860 square feet (0.43 acre).

The waters of the United States proposed to be impacted are ephemeral and none of the impacted areas constitute jurisdictional wetlands. Table 6.2 summarizes impacts to Corps jurisdiction, Exhibit 4 depicts the locations and widths of the various drainages.

Because discharges associated with the project would result in minor impacts to ephemeral drainages subject to Corps jurisdiction, the Los Angeles District of the Corps has issued a conditional authorization for the project under a Nationwide Permit No. 26. This authorization, dated March 27, 2000 is valid until February 11, 2002 and is included as Appendix C.

Out of approximately 469,720 square feet (10.78 acres) of CDFG jurisdiction at the site, construction of the project as proposed would impact approximately 59,885 square feet (1.37 acres) of CDFG jurisdiction of which 42,095 square feet (0.97 acre) consists of vegetated riparian habitat composed of 0.03 acre of willow woodland, and 0.94 acre of coast live oak woodland. Table 6.3 summarizes impacts to CDFG jurisdiction, Exhibit 4 depicts the locations and widths of the various drainages and associated riparian habitat. Two bridge crossings of Devil Canyon would span the drainage and avoid direct impacts to jurisdictional areas.

Table 6.2
Corps Jurisdiction and Impacts

Location	Jurisdictional Area (square feet)			Impacts (square feet)

6.6 INDIRECT IMPACTS

Because the Chatsworth Ridge Estates project is near existing or approved developments to the south, east, and west, portions of the proposed project site have been and continue to be impacted by: (1) past and present residential development and fuel modification; (2) equestrian development and use; (3) unauthorized informal recreational use and access by neighbors; and (4) planting/escape of non-native species, resulting in adverse effects to biological resources. Implementation of the project would result in less incidence of certain indirect effects and increased incidence of others.

Indirect impacts would be associated with all phases of a development project, beginning at the time of initial grading and construction, and continuing in perpetuity. These impacts may occur as a single event, or can interact cumulatively (discussed below) to adversely affect native wildlife, plants, and their habitats.

Increased recreational and residential use can contribute to increased indirect impacts to native plants and vegetation communities. These impacts include further risk of disturbance resulting from vehicle use and human-caused incidences such as fire. Disturbance tends to drive native communities toward a higher percentage of non-native, weedy species, affecting the plant and animal makeup and distribution within a given area. Non-native plants used in landscaping or in livestock feed can escape and degrade natural communities.

Unauthorized recreational or transitory use of the site after buildout would be more controlled than at present; however, not all such recreational or transitory uses can always be controlled. These uses are associated with the following impacts to wildlife (Knight and Gutzwiller 1995):

- Loss of wildlife habitat (cover, foraging, breeding sites) due to human access into vegetated areas;
- Loss of wildlife habitat from destruction of understory/forest floor vegetation resulting from being run over/torn up by mountain bikes, or horses;
- Loss of individuals from being run over or from destruction of aestivation sites (especially important for ground-nesting species);
- Disturbance to or destruction of unique/sensitive/rare habitat types (e.g., riparian, springs, habitat links, corridors, etc.). Aquatic habitats are especially vulnerable and, seem to be especially attractive to drivers of all types of vehicles who seek out water to ford;
- Soil compaction/disturbances and erosion resulting in a loss of vegetative productivity;
- Destruction of food, cover, and breeding habitats;
- Increased zone of displacement and the associated impacts of flight responses;
- When components of soil, vegetation, or aquatic resources are changed, food supply, food availability, and shelter characteristics are impacted. Impacts to food and shelter ultimately affect behavior, survival, reproduction, and distribution of individuals, and wildlife communities and populations; and
- Adding to the acreage of unvegetated areas and disturbance zones, leaving less total acreage of undisturbed natural areas.

Within or immediately adjacent to developed areas, wildlife can be disturbed by light and noise, and may be killed by vehicles, cats, dogs, or humans. Domestic cats are particularly skilled predators, taking mammals, reptiles, amphibians, and birds. Generalist animals such as coyotes, opossums, skunks, raccoons, ravens, and starlings can benefit from human settlement,

but other less-adaptable species rarely persist in an area after it is developed. Proposed open space areas, such as Devil Canyon, have sufficient cover and isolation from many of the indirect effects of development to support a suite of small wildlife species. Other areas, particularly small, open space “islands” or “edges” next to or surrounded by development, may be subject to more severe indirect effects. The project would limit access to the open space to the north and west.

The effects of night lighting on wildlife utilizing the adjacent open areas of the project site and off site are of potential concern. Streetlights on the project site have been designed to minimize light-related disturbance to wildlife. Light poles will be 14 feet high instead of 26 feet high and all streetlights potentially affecting open space areas will be fitted with baffles to eliminate direct shine into open space areas. While there will be a minor amounts of light coming from homes, vehicles, and other sources, these light sources would likely have little adverse effect on open space habitats, especially high-quality habitat in canyons below the development.

The project proposes to remove eucalyptus and other non-native plant species, include non-invasive or native landscaping in the project landscaping plan, design multi-use trails, channel public access into predetermined and suitable trails while restricting access to others, and provide for regular management, maintenance, and oversight of the open space areas. Therefore, indirect effects are considered adverse, but less than significant.

The proposed project could have a moderate impact on surface water quality during the construction period. A storm water pollution prevention plan will be in place to direct prevention and/or minimization of storm runoff from the work site during construction and thereby mitigate that impact. However, an accidental or otherwise unforeseen discharge could cause a temporary increase in suspended sediments and/or turbidity, resulting in impacts to aquatic organisms. For example, the discharge of sediments could affect developing amphibian embryos by smothering (Sweet 1992) and reduce available pool habitat (reductions in water depth) for egg-laying and larvae. Increased urban runoff would likely result in increased growth of plants in low-lying areas. In many instances increased vegetative growth could potentially result in a potentially beneficial increase of native riparian and/or wetland vegetation and a shift toward longer periods of flow in the streambeds. If increased flows in the future contribute to an increase in non-native vegetation, native plant and animal communities would likely be adversely impacted.

After construction, sediment runoff from the site is expected to be less than pre-project conditions due to a reduction in erodible surfaces on the site. Storm water runoff is expected to undergo long-term water quality changes following project buildout and transformation into an urban setting. A Standard Urban Stormwater Mitigation Plan (SUSMP) shall be developed to ensure that pollutants from runoff would not lower the surface water quality of water courses on the site and downstream. The runoff will contain increased concentrations of nitrogen and phosphorus because of the use of fertilizers by homeowners. Oil and grease concentrations would increase because of motor vehicle use. Increased loading of organic material and the associated biological oxygen demand (BOD) are also likely. Bacteria, including the coliform group may also exhibit increased concentrations. These pollutants would slightly lower the water quality of watercourses on the site and downstream. However, these impacts would only be expected infrequently during episodes of storm water runoff from the project site and are not likely to result in significant impacts to biological resources. A Stormwater Pollution Prevention Plan (SWPPP) will be in place to direct prevention and/or minimization of stormwater runoff from the work site during construction and thereby mitigate that impact.

Nuisance flows will likely carry the largest load of pollutants. Where nuisance flows are directed to wetlands, swales, canyons, or other areas where the nuisance flows would percolate, evaporate, or be taken up by wetland/riparian vegetation, impacts to wildlife and water quality would be considered minor. In major storm events, nuisance flows would mix with the storm flows and would discharge in a diluted form. Impacts resulting from urban nuisance flows are considered to be below a level of significance. As stated above, a Stormwater Pollution Prevention Plan (SWPPP) will be in place to direct prevention and/or minimization of stormwater runoff from the work site during construction and thereby mitigate that impact.

6.7 CUMULATIVE IMPACTS

The proposed project is within a rapidly urbanizing area near protected public lands. The approved Porter Ranch development to the east will likely result in the loss of approximately 1,500 acres of open space and native habitats. The Indian Springs development to the west is less dense, but has resulted in the modification of similar habitats to urban uses. Impacts to Corps and CDFG jurisdiction on other sites are subject to mitigation requirements.

The proposed project would not contribute to a cumulative loss or degradation of Corps and CDFG jurisdiction, sensitive vegetation associations or habitats, or federally- and/or state-listed plants or animals. In addition, local open space, particularly in the protected portions of the project site and elsewhere in the vicinity of the Santa Susana Pass, will preserve common wildlife species and vegetation associations with the likely result that most, if not all, will remain common in the region. However, the project would result in adverse but not significant impacts to common wildlife species and ashy rufous-crowned sparrow, and adverse but not significant cumulative impacts to Plummer's mariposa lily. The applicant is proposing to dedicate a strip of land along the northern portion of the project site to the Santa Monica Mountains Conservancy, which will effectively restrict any future access to, and development of areas north of the project site.

7.0 MITIGATION MEASURES

7.1 SENSITIVE VEGETATION COMMUNITIES

As stated in Section 6.1, implementation of the proposed project would not result in significant impacts with regard to the following sensitive vegetation communities: chamise chaparral, coastal sage scrub, oak woodland/willow woodland, or non-native/previously disturbed areas. However, significant impacts could occur with regard to coast live oak woodland and willow woodland. Therefore, mitigation measures have been included to reduce impacts to these sensitive communities to less than significant.

The applicant is proposing, as a component of the mitigation program to reduce impacts to less than significant level through the acquisition of a minimum 60 acre parcel of undisturbed natural open space in the immediate vicinity of the project site. This parcel will be dedicated to a public resource protection agency prior to initiation of project grading operations and will be located either adjacent to the project site or adjacent to existing undisturbed open space. The biological composition of the mitigation parcel shall have, at a minimum, the required amount of high quality habitat to meet mitigation ration requirements as outlined below and in many cases will provide in excess of required mitigation requirements.

With the exception of mitigation measures addressing onsite preservation or habitat creation, the following mitigation measures will be primarily implemented on the off-site mitigation parcel and are recommended to ensure biological resource impacts would be less than significant.

Finally, a Storm Water Pollution Prevention Plan (SWPPP) will be in place to direct prevention and/or minimization of stormwater runoff from the work site during construction to prevent/minimize impacts to riparian/wetland vegetation and associated species.

7.1.1 COAST LIVE OAKS

As development occurs around the preserved oak trees, they will become dependent upon the future residents for their care and preservation. All construction activities will be conducted in accordance with the established preservation program. This program was developed to

control the impacts to each tree and to protect them from any unnecessary and unscheduled damage. All oak tree mitigation techniques will be observed on-site by a qualified arborist. The following discussion of recommendations, if followed, should ensure that the saved oak trees would remain as valuable assets to the community.

Tree Protection

The trees within 50 feet of proposed grading shall be fenced at their “protected zones”, or at the location of their approved encroachment, with a minimum four foot high chain-link fence, or an acceptable alternative, before any site grading commences. No equipment storage, debris drip, etc. shall take place within any tree-protected zone. This fence shall not be moved and/or removed without certification from a qualified arborist and approved by the Los Angeles County Forester. Any brush clearance within the dripline areas will be completed by handwork only.

Dead Wood Removal and/or Pruning (*only if needed*)

Dead wood removal is the removal of dead wood from within the tree, while structural pruning for clearance and/or safety pruning of hazardous limbs should only be done if approved by the Los Angeles County Forester. All pruning shall be done by a qualified arborist on an “as needed basis” and is subject to the approval by the Los Angeles County Forester. Pruning wounds shall not be sealed unless required by the Los Angeles County Forester. Climbing “gaffs” shall not be used by any tree climber except to reach an injured climber or when removing a tree.

Water and Fertilization (*only if needed*)

The water and fertilization frequency shall be done on an “as needed basis” and is subject to the approval of the Los Angeles County Forester. Native oak trees are in a dormant state during the summer months and do not require regular or constant watering (or fertilizing). Watering is normally contemplated only following long periods of extreme drought. Fertilization of these native oak trees may be detrimental in general drought conditions. The addition of fertilizer into a maintenance program may promote temporary growth “flushes” at a time when the tree would normally be maintaining regular growth or to even reduce the number of green leaves present. The greater amount of foliage the tree has, the higher the needs of watering requirements may occur.

Disease and Pests (*only if needed*)

During all phases of construction, the health of the trees shall be monitored by a qualified arborist for signs and symptoms of disease. These problems, if they arise, shall be remedied as prescribed. If bees are encountered and they become a problem in any on-site oak tree, they shall be removed by a professional beekeeper.

Grading Within the Protected Zone

No grading shall take place within the oak tree protected zones without the approval of the Los Angeles County Forester. If grading is approved within the protected zone, a qualified arborist shall be present during all work. This shall initially be done by handwork. All pruned roots shall consist of clean-cut surfaces at a 90 degree angle and shall not be sealed unless approved by the Los Angeles County Forester.

Other Considerations

The leaflet (P09-88) entitled "Oak Tree Care and Maintenance," as prepared by the Los Angeles County Fire Department – Forestry Division should be utilized as reference material. Grade stakes or anything else shall not be nailed to any native oak tree. Natural leaf mulch within any native oak dripline shall not be removed unless absolutely necessary. Herbicides shall not be applied within the protected zone of any native oak tree. The dust accumulation on the tree's foliage (from nearby construction) will be hosed off during construction, under the advice from a qualified arborist.

Oak Tree Mitigation Measures

Oak tree replacement mitigation shall consist of a minimum 130 15-gallon oak specimen trees (2:1 replacement with 15 gallon trees) to be planted on the project site or offsite mitigation parcel as replacement trees for the required 65 oak tree removals (none of which are heritage oak trees). In addition, 2.6 acres of coast live oak habitat will be provided on-site or off-site, representing a 2:1 replacement for the loss of habitat value associated with the impacted oak habitat. Replacement trees shall be properly maintained for a period of two years and replaced by this project developer if fatality occurs during that period. The landscape architect/designer for this project shall design into the "native undisturbed landscape area" with these replacement oak trees. The irrigation system to water these newly planted

replacement trees shall be compatible with the watering requirement of the project's indigenous oak trees. Any County approved work within the protected zones of the saved oak trees, including pruning, shall be under the observation of a qualified arborist. Copies of the final *Oak Tree Report* and the Los Angeles County approved Oak Tree Permit shall be maintained on-site during all site construction.

Finally, All eucalyptus shall be removed from open space portions of the project site to enhance the biological values of open space areas, reduce the risk of a canopy fire, and prevent further encroachment of eucalyptus into native habitats. To avoid impacts to nesting birds such removal shall be implemented outside of the avian nesting season from March 15th to August 15th.

7.1.2 COASTAL SAGE SCRUB

Although impacts to 2.39 acres of degraded coastal sage scrub are not considered significant, the applicant proposes to mitigate the loss of this habitat which is utilized by wildlife through off-site preservation, on the mitigation parcel of a minimum of 4.78 acres of coastal sage scrub or coastal sage scrub/chaparral ecotone habitat.

7.1.3 WILLOW WOODLAND

The applicant shall mitigate impacts to 0.03 acre of on-site willow woodland based on recommendations of the project biologist (see Appendix G of this Draft EIR) and to the satisfaction of the CDFG. This mitigation measure will be implemented on the mitigation parcel with 0.12 acre (representing a 4:1 ratio).

7.2 GENERAL WILDLIFE AND WILDLIFE MOVEMENT CORRIDORS

Although as stated in Section 6.2, project implementation would not result in significant impacts to regional wildlife movement or local wildlife populations, the following mitigation measure is recommended to ensure that impacts would remain less than significant. Light poles shall be 14 feet high instead of 26 feet high and all streetlights potentially affecting open space areas shall be fitted with baffles to eliminate direct shine into open space areas.

7.3 SENSITIVE PLANTS

As stated in Section 6.3 no significant impacts would occur to the following sensitive plants: Braunton's milkvetch, Nevin's barberry, Catalina mariposa lily, slender mariposa lily, San Fernando Valley spineflower, slender-horned spineflower, Robinson's pepper grass, ocellated Humboldt lily, and Fish's milkwort.

It has been determined that significant impacts would occur to Plummer's mariposa lily with implementation of the proposed project. Therefore, the following mitigation measures, developed by Envicom Corporation in a detailed mitigation program are recommended to reduce impacts to less than significant.¹

Impacts to Plummer's mariposa lily shall be mitigated through a 2:1 replacement of impacted individuals for a total of 4,000 for an impact of 2,000 and an additional 1:1 replacement through preservation. Relocated Plummer's mariposa lily will be planted on the mitigation parcel. A qualified biologist/botanist shall oversee all aspects of this mitigation plan including bulb and seed collection and transplanting, per the recommendations of the project biologist (included in Appendix G of this Draft EIR). Seed collection shall occur prior to collection of bulbs from all plants within the development envelope. The Plummer's mariposa lily mitigation plan shall be reviewed and approved by the Los Angeles County Department of Regional Planning, prior to issuance of grading permits. Maintenance of relocated Plummer's mariposa lilies shall be monitored for a period of five years. Annual monitoring reports shall be submitted to CDFG and the Los Angeles County Department of Regional Planning. The Plummer's mariposa lily salvage, propagation and transplanting program is designed to retrieve a sizable portion of the on-site bulbs for use in both on-site and off-site habitat enhancement. Another component of this effort is researching and documenting methods that lead to successful long-term establishment of transplanted bulbs. This includes bulbs collected and transplanted directly to a site within the same year, stored bulbs, and bulbs grown from seed in a nursery. The salvage program will consist of the following components:

- Prior to grading, seed shall be collected and all flagged/mapped bulbs, and any uncovered during removal shall be salvaged. A minimum of 4,000 bulbs shall be collected (this represents a 2:1 replacement ratio). If 4,000 bulbs do not inhabit the project site, all bulbs found shall be collected.
- All bulbs shall be stored at a qualified native plant nursery.
- 40 percent of the bulbs shall be used for transplantation to on-site and off-site preserved habitat in the fall/winter immediately following salvage.

¹ Envicom Corporation, 2001. *Chatsworth Ridge Estates Mitigation Plan, Plummer's Mariposa Lily and Sensitive Biological Resources*.

- 20 percent of the bulbs shall be propagated at a qualified native plant nursery to collect seed for starting new plants for transplantation to preserved areas both on-site and off-site.
- 40 percent of bulbs shall be stored for a period of five (5) years for annual or bi-annual planting in preserved areas, as determined by a qualified biologist.
- All transplanted bulbs shall be maintained, including weed control.
- Monitoring and reporting shall be conducted.

7.4 SENSITIVE WILDLIFE: PRECONSTRUCTION MITIGATION MEASURES

As stated in Section 6.4 no significant impacts would occur to the following sensitive wildlife: California red-legged frog, San Diego horned lizard, two-striped garter snake, ashy rufous-crowned sparrow, western yellow warbler, southwestern willow flycatcher, coastal California gnatcatcher, and least Bell's vireo. Also; while project impacts do not require compensation for impacts to the San Diego horned lizard or the ashy rufous-crowned sparrow, the proposed acquisition of off-site habitat as mitigation for the Plummer's mariposa lily would directly benefit these two still-common species.

Prior to any construction activity, the applicant shall have a qualified biologist survey the project site for the presence of any occupied raptor nests, including Cooper's hawks as protected by the Migratory Bird Treaty Act. If such a nest is found, it will be avoided and protected until nesting activity has ended to ensure compliance with Section 3503.5 of the California Fish and Game Code based on the recommendations of the project biologist (see Appendix G of this Draft EIR). During nesting (March 15th to August 15th) occupied nests shall be avoided through implementation of a 300 foot buffer zone for nesting bird and a 500 foot buffer zone for nesting raptors. Should construction activities encroach into these identified buffer zones, noise barriers shall be constructed to minimize noise impacts to the birds and ensure that noise levels do not exceed 65db CNEL.

7.5 JURISDICTIONAL RESOURCES

Impacts to Corps jurisdiction total 0.43 acre of ephemeral streambed and includes no impacts to jurisdictional wetlands. Impacts to CDFG jurisdiction totals 1.37 acres of which 0.97 acres consist of vegetated riparian habitat consisting of 0.03 acre of willow woodland habitat, 0.94

acre of coast live oak forest and 0.40 acre of unvegetated ephemeral channel. The applicant shall be responsible for the development of a detailed mitigation plan in accordance with the Corps' Mitigation and Monitoring Guidelines and would include those measures required by CDFG. The objective of the mitigation plan is to ensure no net loss of habitat values from the project. The plan would typically include the following elements:

- Responsibilities and qualifications of the personnel to implement and supervise the plan
- Plant material seed mixtures
- Site preparation and planting implementation
- Performance criteria
- Monitoring and maintenance plan
- Long term preservation of the site

This mitigation monitoring plan shall be subject to approval by the Corps, CDFG, the Regional Water Quality Control Board (RWQCB), SMMC, and Los Angeles County. However, if unforeseen circumstances require the use of alternate on-site or off-site planting locations, these locations may be changed pursuant to the recommendations of the project biologist, the City and responsible agencies. If an annual performance criterion is not met for any portion of the mitigation project in any year, or if the final success criteria are not met, the applicant will prepare an analysis of the cause(s) of failure and, if determined necessary by the Corps and/or CDFG, propose remedial action for approval. The applicant will fund planning, implementation, and monitoring of any contingency procedures that may be required to achieve mitigation goals. The applicant will be responsible for implementing and monitoring any contingency procedures. The applicant may assign these responsibilities to an appropriate contractor, but will retain ultimate responsibility for implementing and monitoring any contingency procedures.

Planting Plan

To the extent that habitat creation/revegetation is included as a component of the mitigation program, it will incorporate willow woodland and coast live oak woodland as a reflection of the project site's existing vegetation communities. The areas designed to mitigate for impacts to Corps and CDFG jurisdiction shall be planted with red willow (*Salix laevigata*), arroyo willow (*Salix lasiolepis*), black cottonwood (*Populus balsamifera* ssp. *trichocarpa*), Fremont cottonwood (*Populus fremontii*), western sycamore (*Platanus racemosa*), and mule fat (*Baccharis salicifolia*). Understory species shall include California rose (*Rosa californica*) and California

blackberry (*Rubus ursinus*). Table 7.1 provides a list of the container stock required for this portion of the planting.

Plants in one-gallon cans shall be the preferred container stock size due to their ability to become established quickly. All container stock except for the willows and mule fat shall be inoculated with mycorrhizae or will be planted with mycorrhizal inoculum. Mycorrhizae are specialized fungi found on plant roots. A symbiotic relationship exists between plant roots and mycorrhizae wherein the plants benefit from the increased ability to take up nutrients and withstand drought when mycorrhizae are present. This relationship is essential to the growth rate, well-being, and longevity of most native plant communities. Plant utilization of mycorrhizal fungi markedly increases the success of revegetation on disturbed or degraded lands. All appropriate container-grown plants, except those known to be non-host species shall be inoculated with mycorrhizal fungi before delivery to the job site.

Seeded species include ragweed (*Ambrosia psilostachya*), mugwort (*Artemisia douglasiana*), Table 7.1 provides a list of the seed required for this portion of the planting. The seeds shall be hydroseeded or raked into the upper one-inch of the soil surface and mycorrhizal inoculum shall be incorporated during the seeding process because mycorrhiza is likely scarce or absent from soils dominated by non-native species.

Container stock shall be laid out in a natural configuration within planting areas. Prior to plant installation, individual planting locations in the field shall be flagged with pin flags by the project monitor. The flags shall be color coded by species. A list of species referencing their color code shall be provided to the installation contractor by the project monitor prior to plant installation.

Irrigation Plan

A temporary irrigation system placed on grade shall be utilized to supplement natural rainfall, stream flows, and ground water. The system shall provide overhead application of water using spray heads in order to reduce the potential for erosion. Following the establishment of the planted and seeded species for two years and the passage of one summer without irrigation, the irrigation system shall be removed at the discretion of the project monitor.

Table 7.1
Plant Palette for Mitigation for Impacts to Corps and CDFG Jurisdiction

Botanical Name	Common Name	Stock Type	Plant Spacing	No./Acre	Total Plants ^a
WILLOW WOODLAND (up to 0.15 ac)					
<i>Salix lasiolepis</i>	arroyo willow	1-gal	10' o.c.	262	TBD

Seed		Lbs./Acre	Total Lbs.	Comments	
<i>Ambrosia psilostachya</i>	ragweed	3	12	-	
<i>Artemisia douglasiana</i>	mugwort	4	15.5	-	
<i>Rosa californica</i>	wild rose	2	7.75	3 mos. cold stratification in refrigerator; keep moist in sealed container; check for germination	

a An additional ten percent of each species (above and beyond the figures shown here) will be ordered and available on hold at the nursery charged with providing plant material for this project. This availability will be necessary for the first six months of project life.

Source: Glenn Lukos Associates, Inc., 2000.

Maintenance Activities

The purpose of this program is to ensure the success of the mitigation planting. Maintenance will occur over the life of the project. The applicant shall be responsible for financing and carrying out maintenance activities. The applicant may assign the maintenance responsibilities to an appropriate contractor, but will retain ultimate responsibility for maintenance of the mitigation site. As the installation is completed the project monitor shall schedule a meeting

with key members of the landscape maintenance crew in order to identify proper maintenance procedures. The following tasks shall be performed as general maintenance duties:

- **Contractor Education:** The contractor must schedule a meeting with the project monitor previous to the start of the maintenance period in order clearly identify proper maintenance procedures.
- **Irrigation:** The irrigation system shall be checked periodically by the maintenance contractor in order to ensure its proper functioning and to check for damage by vandals or wildlife. Broken or poorly functioning parts shall be replaced immediately.
- **Weeding:** The mitigation plantings shall be maintained free of weeds through the five year monitoring period. Weed species known to not present a serious threat to the successful establishment of the desired native species may be left in place, but only if their presence does not preclude the ultimate establishment of the native species over at least 80-percent of the mitigation site.
- **Plant Replacement:** All plants terminally diseased or dead, as determined by the project monitor, shall be replaced within two weeks by the installation contractor for a 120-day period after installation, and thereafter shall be replaced as required by the project monitor on an annual basis. Unless substitutions are approved by the project monitor, the replacement plants shall be of the same species, spacing and size as specified for plants being replaced. Any substitutions shall be reported in the annual report (see below).
- **Pruning and Staking:** Pruning and staking of trees and shrubs is not necessary. Dead wood should remain where it has fallen, it plays an important role in habitat creation and in soil formation.
- **Pest Control:** Plants should be monitored for herbivory and diseases. Biological control of insect pests is preferred and badly damaged plants should be removed to prevent spread of the problem.
- **Weekly weed control maintenance** shall be necessary for at least the first six months of project life. Uncontrolled weeds would quickly out-compete many of the desired native plant species. As the first year passes into the summer and fall the weed problem is expected to decrease, and, depending on the health and spread of the desired plants, the weed maintenance schedule shall likely decrease the second year of project life.

Monitoring Plan

Habitat creation or revegetation areas, to the extent that they are incorporated into the mitigation program, will be monitored for five years. Monitoring will consist of routine site visits to inspect the functioning of the irrigation system and the health of the container stock and seed plantings. Percent coverage of the slopes will be determined each year on an annual

basis. If percent coverage does not satisfy the following percent coverages at the end of each year of monitoring, then remedial measures may be taken in order to ensure that the following year's percent coverage goal is satisfied: Year One - 20%, Year Two - 35%, Year Three - 50%, Year Four - 65%, and Year Five - 80%. If a portion of the mitigation areas attains the fifth-year percent coverage criteria before the end of the fifth year and after the plantings have survived at least one summer without supplemental irrigation, then the applicant may request that the remaining portion of the monitoring period be waived.

Monitoring will be performed by the project monitor. The success of mitigation is usually measured in percent coverage by target species. While a fully successful mitigation plan might be viewed as one that results in 100-percent coverage, such coverage is unlikely. Natural habitats rarely exhibit 100-percent coverage, but rather include a considerable proportion of open spaces. While this monitoring program uses percent coverage criteria, it is noted that determination of successful coverage is expected to be relative to other similar native habitats typical of the region.

Percent cover determinations will be made using standard point-intercept transect measurements or another suitable visual method. Scaled aerial photography may also be employed in order to approximate percent cover and overall progress of the plantings.

At the end of each of the five monitoring period growing seasons, an annual report will be prepared for submittal to the Corps, RWQCB, CDFG, and Los Angeles County. These reports will assess both attainment of yearly target criteria and progress toward final success criteria. These reports will include the following:

- A list of names, titles, and companies of all persons who prepared the content of the annual report and participated in monitoring activities for that year.
- A copy of the Corps permit, Water Quality Certification, Streambed Alteration Agreement and any attachments including Special Conditions and subsequent Letters of Modification, Amendments or Extensions.
- An analysis of all qualitative monitoring data.
- Copies of monitoring photographs.
- Maps identifying monitoring areas, transects, planting zones, etc. as appropriate.

Routine monitoring will be conducted once each month for the first twelve months following project installation and then quarterly thereafter. Field work for the annual reports will be

conducted on or about the anniversary of the completion of installation for five years. The annual report will be submitted within one month of the completion of field surveys.

Completion of Mitigation

When the initial monitoring period is complete, and if the applicant believes final success criteria have been met, the applicant will notify the Corps and the CDFG when submitting the annual report that documents this completion. Following receipt of the report, the applicant will, at the request of the Corps or the CDFG, provide access and guidance through the project site to confirm the adequate completion of the mitigation effort.

7.6 SIGNIFICANCE AFTER MITIGATION

After implementation of the aforementioned mitigation measures, the project would not result in significant impacts to Corps/CDFG jurisdiction, coast live oak woodland, willow woodland, or Plummer's mariposa lily. In addition, although there would be no significant impacts to the two-striped garter snake, western yellow warbler, ashy rufous-crowned sparrow, common wildlife, or wildlife movement corridors, each of these would be directly benefited by the proposed off-site acquisition of high quality oak riparian and adjacent upland habitat.

APPENDIX A

FAUNAL AND FLORAL COMPENDIA

APPENDIX A
FAUNAL AND FLORAL COMPENDIA
INTRODUCTION TO FLORAL AND FAUNAL SURVEY

Floral taxonomy used in this report follows the Jepson Manual (Hickman 1993) and, for sensitive species, the California Native Plant Society's Rare Plant Inventory (5th Edition) (Skinner and Pavlik 1994). Additional common plant names are taken from Munz (1974), Beauchamp (1986), and Roberts (1998). Vertebrates identified in the field by sight, calls, tracks, scat, or other signs are cited according to the nomenclature of Collins (1997) for amphibians and reptiles, AOU (1998) for birds, and Jones et al. (1992) for mammals.

FAUNAL COMPENDIUM¹

LEGEND

STATUS

- + Presence of animals noted by direct sighting, call identification or observation of tracks, scat or other signs.
- * Non-native

TERRESTRIAL VERTEBRATES

AMPHIBIANS

SALAMANDRIDAE - NEWTS

Taricha torosa
California newt

PLETHODONTIDAE - LUNGLESS SALAMANDERS

Ensatina eschscholtzi
ensatina
Aneides lugubris
arboreal salamander
Batrachoseps nigriventris
black-bellied slender salamander
Batrachoseps pacificus
Pacific slender salamander

BUFONIDAE - TRUE TOADS

- + *Bufo boreas*
western toad

1

List includes species observed or expected to occur on or in the immediate vicinity of the site.

HYLIDAE - TREEFROGS

- + *Pseudacris regilla*
Pacific treefrog

REPTILES

GEKKONIDAE - GECKOS

- Coleonyx variegatus*
San Diego banded gecko

IGUANIDAE - IGUANID LIZARDS

- + *Sceloporus occidentalis*
western fence lizard
- Sceloporus graciosus*
sagebrush lizard
- + *Uta stansburiana*
side-blotched lizard
- Phrynosoma coronatum*
coast horned lizard

SCINCIDAE - SKINKS

- + *Eumeces skiltonianus*
western skink
- Eumeces gilberti*
Gilbert skink

TEIIDAE - WHIPTAIL LIZARDS

- + *Cnemidophorus tigris*
western whiptail

ANGUIDAE - ALLIGATOR LIZARDS

- + *Gerrhonotus multicarinatus*
southern alligator lizard

ANNIELLIDAE - CALIFORNIA LEGLESS LIZARDS

- Anniella pulchra*
California legless lizard

LEPTOTYPHLOPIDAE - SLENDER BLIND SNAKES

Leptotyphlops humilis
western blind snake

BOIDAE - PYTHONS AND BOAS

Charina bottae
rubber boa
Lichanura trivirgata
rosy boa

COLUBRIDAE - COLUBRID SNAKES

- + *Diadophis punctatus*
ringneck snake
- Coluber constrictor*
racer
- Masticophis flagellum*
coachwhip
- + *Masticophis lateralis*
California whipsnake
- Salvadora hexalepis*
western patch-nosed snake
- Arizona elegans*
glossy snake
- + *Pituophis melanoleucus*
gopher snake
- Lampropeltis getulus*
common kingsnake
- Lampropeltis zonata*
California mountain kingsnake
- Thamnophis hammondi*
two-striped garter snake
- Thamnophis sirtalis*
common garter snake
- Tantilla planiceps*
California black-headed snake
- Trimorphodon biscutatus*
lyre snake
- Hypsiglena torquata*
night snake

VIPERIDAE - VIPERS

- + *Crotalus atrox*
western diamondback rattlesnake
- Crotalus viridis*
western rattlesnake

BIRDS

ARDEIDAE - HERONS

- Bubulcus ibis*
cattle egret

CATHARTIDAE - NEW WORLD VULTURES

- + *Cathartes aura*
turkey vulture

ACCIPITRIDAE - HAWKS

- Elanus leucurus*
white-tailed kite
- Circus cyaneus*
northern harrier
- + *Accipiter striatus*
sharp-shinned hawk
- + *Accipiter cooperii*
Cooper's hawk
- + *Buteo lineatus*
red-shouldered hawk
- + *Buteo jamaicensis*
red-tailed hawk
- Buteo regalis*
ferruginous hawk

FALCONIDAE - FALCONS

- + *Falco sparverius*
American kestrel
- Falco columbarius*
merlin
- Falco mexicanus*
prairie falcon

Falco peregrinus
peregrine falcon

PHASIANIDAE - PHEASANTS & QUAILS

+ *Callipepla californica*
California quail

CHARADRIIDAE - PLOVERS

Charadrius vociferus
killdeer

COLUMBIDAE - PIGEONS & DOVES

+* *Columba livia*
rock dove
Columba fasciata
band-tailed pigeon
+ *Zenaida macroura*
mourning dove

CUCULIDAE - CUCKOOS & ROADRUNNERS

+ *Geococcyx californianus*
greater roadrunner

TYTONIDAE - BARN OWLS

+ *Tyto alba*
barn owl

STRIGIDAE - TRUE OWLS

Otus kennicottii
western screech-owl
+ *Bubo virginianus*
great horned owl
Speotyto cunicularia
burrowing owl

CAPRIMULGIDAE - GOATSUCKERS

Phalaenoptilus nuttallii
common poorwill

APODIDAE - SWIFTS

- + *Chaetura vauxi*
Vaux's swift
- Aeronautes saxatalis*
white-throated swift

TROCHILIDAE - HUMMINGBIRDS

- Archilochus alexandri*
black-chinned hummingbird
- + *Calypte anna*
Anna's hummingbird
- + *Calypte costae*
Costa's hummingbird
- + *Selasphorus sasin*
Allen's hummingbird

PICIDAE - WOODPECKERS

- + *Melanerpes formicivorus*
acorn woodpecker
- Melanerpes lewis*
Lewis' woodpecker
- + *Sphyrapicus ruber*
red-breasted sapsucker
- + *Picoides nuttallii*
Nuttall's woodpecker
- + *Picoides pubescens*
downy woodpecker
- Picoides villosus*
hairy woodpecker
- + *Colaptes auratus*
northern flicker

TYRANNIDAE - TYRANT FLYCATCHERS

Contopus borealis
olive-sided flycatcher

- + *Contopus sordidulus*
western wood-pewee
- Empidonax traillii*
willow flycatcher
- Empidonax hammondii*
Hammond's flycatcher
- + *Sayornis nigricans*
black phoebe
- + *Sayornis saya*
Say's phoebe
- + *Myiarchus cinerascens*
ash-throated flycatcher
- Tyrannus vociferans*
Cassin's kingbird
- + *Tyrannus verticalis*
western kingbird

ALAUDIDAE - LARKS

Eremophila alpestris
horned lark

HIRUNDINIDAE - SWALLOWS

- + *Tachycineta bicolor*
tree swallow
- + *Tachycineta thalassina*
violet-green swallow
- + *Stelgidopteryx serripennis*
northern rough-winged swallow
- + *Hirundo pyrrhonota*
cliff swallow
- Hirundo rustica*
barn swallow

CORVIDAE - JAYS & CROWS

- + *Aphelocoma coerulescens*
western scrub-jay
- + *Corvus brachyrhynchos*
American crow
- + *Corvus corax*
common raven

PARIDAE - TITMICE

- + *Parus inornatus*
plain titmouse

AEGITHALIDAE - BUSHTITS

- + *Psaltriparus minimus*
bushtit

SITTIDAE - NUTHATCHES

- Sitta canadensis*
red-breasted nuthatch
- Sitta carolinensis*
white-breasted nuthatch

CERTHIDAE - CREEPERS

- Certhia americana*
brown creeper

TROGLODYTIDAE - WRENS

- Campylorhynchus brunneicapillus*
cactus wren
- Salpinctes obsoletus*
rock wren
- Catherpes mexicanus*
canyon wren
- + *Thryomanes bewickii*
Bewick's wren
- + *Troglodytes aedon*
house wren

MUSCICAPIDAE - KINGLETS, GNATCATCHERS, THRUSHES & BABBLERS

- + *Regulus calendula*
ruby-crowned kinglet
- + *Polioptila caerulea*
blue-gray gnatcatcher
- Polioptila californica californica*
coastal California gnatcatcher

- Sialia mexicana*
western bluebird
- Catharus ustulatus*
Swainson's thrush
- + *Catharus guttatus*
hermit thrush
- + *Turdus migratorius*
American robin
- + *Chamaea fasciata*
wrentit

MIMIDAE - THRASHERS

- + *Mimus polyglottos*
northern mockingbird
- + *Toxostoma redivivum*
California thrasher

MOTACILLIDAE - PIPITS

- Anthus rufescens*
American pipit

BOMBYCILLIDAE - WAXWINGS

- Bombycilla cedrorum*
cedar waxwing

PTILOGONATIDAE - SILKY-FLYCATCHERS

- + *Phainopepla nitens*
phainopepla

LANIIDAE - SHRIKES

- Lanius ludovicianus*
loggerhead shrike

STURNIDAE - STARLINGS

- +* *Sturnus vulgaris*
European starling

VIREONIDAE - VIREOS

- + *Vireo solitarius*
solitary vireo
- + *Vireo huttoni*
Hutton's vireo
- Vireo gilvus*
warbling vireo

EMBERIZIDAE- WOOD WARBLERS, TANAGERS, BUNTINGS & BLACKBIRDS

- Vermivora celata*
orange-crowned warbler
- Vermivora ruficapilla*
Nashville warbler
- + *Dendroica petechia*
yellow warbler
- + *Dendroica coronata*
yellow-rumped warbler
- Dendroica nigrescens*
black-throated gray warbler
- + *Dendroica townsendi*
Townsend's warbler
- Dendroica occidentalis*
hermit warbler
- Geothlypis trichas*
common yellowthroat
- + *Wilsonia pusilla*
Wilson's warbler
- Icteria virens*
yellow-breasted chat
- + *Pheucticus melanocephalus*
black-headed grosbeak
- + *Piranga ludoviciana*
western tanager
- Guiraca caerulea*
blue grosbeak
- Passerina amoena*
lazuli bunting
- + *Pipilo crissalis*
California towhee
- + *Pipilo erythrophthalmus*
spotted towhee

- + *Aimophila ruficeps*
rufous-crowned sparrow
- Amphispiza belli*
sage sparrow
- Spizella passerina*
chipping sparrow
- Pooecetes gramineus*
vesper sparrow
- Chondestes grammacus*
lark sparrow

- Passerculus sandwichensis*
savannah sparrow
- Ammodramus savannarum*
grasshopper sparrow
- Passerella iliaca*
fox sparrow
- + *Melospiza melodia*
song sparrow
- + *Melospiza lincolnii*
Lincoln's sparrow
- + *Zonotrichia atricapilla*
golden-crowned sparrow
- + *Zonotrichia leucophrys*
white-crowned sparrow
- + *Junco hyemalis*
dark-eyed junco
- Sturnella neglecta*
western meadowlark

ICTERIDAE - BLACKBIRDS

- Agelaius phoeniceus*
red-winged blackbird
- Xanthocephalus xanthocephalus*
yellow-headed blackbird
- Euphagus cyanocephalus*
Brewer's blackbird
- + *Molothrus ater*
brown-headed cowbird
- + *Icterus galbula*
Hooded oriole
- + *Icterus bullockii*
Bullock's oriole

FRINGILLIDAE - FINCHES

- Carpodacus purpureus*
purple finch
- + *Carpodacus mexicanus*
house finch
- + *Carduelis psaltria*
lesser goldfinch
- Carduelis lawrencei*
Lawrence's goldfinch

- + *Carduelis tristis*
American goldfinch

PASSERIDAE - OLD WORLD SPARROWS

- +* *Passer domesticus*
house sparrow

MAMMALS

DIDELPHIDAE - NEW WORLD OPOSSUMS

- * *Didelphis virginiana*
Virginia opossum

SORICIDAE - SHREWS

- Sorex ornatus*
ornate shrew
- Notiosorex crawfordi*
desert shrew

TALPIDAE - MOLES

- Scapanus latimanus*
broad-footed mole

VESPERTILIONIDAE - EVENING BATS¹

- Myotis evotis*
long-eared myotis
- Myotis thysanodes*
fringed myotis

Myotis volans
long-legged myotis
Myotis californicus
California myotis
Myotis leibii
small-footed myotis
Eptesicus fuscus
big brown bat
Lasiurus blossevillii
western red bat
Lasiurus cinereus
hoary bat
Euderma maculatum
spotted bat
Pipistrellus hesperus
western pipistrelle
Plecotus townsendii
Townsend's big-eared bat
Antrozous pallidus
pallid bat

MOLOSSIDAE - FREE-TAILED BATS²

Tadarida brasiliensis
Brazilian free-tailed bat
Eumops perotis
western mastiff bat

LEPORIDAE - HARES & RABBITS

- + *Sylvilagus audubonii*
desert cottontail
- + *Sylvilagus bachmani*
brush rabbit
- Lepus californicus*
black-tailed jackrabbit

² The site is within the range of a number of bat species in several families, but it is unlikely that all are present. As their distribution varies according to season, and as the precise habitat requirements of each species are not well known, it is difficult to determine which species are present on the property.

SCIURIDAE - SQUIRRELS

- + *Tamias merriami*
Merriam's chipmunk
- + *Spermophilus beecheyi*
California ground squirrel
- Sciurus griseus*
western gray squirrel

GEOMYIDAE - POCKET GOPHERS

- + *Thomomys bottae*
Botta's pocket gopher

HETEROMYIDAE - POCKET MICE & KANGAROO RATS

- Chaetodipus californicus*
California pocket mouse
- Dipodomys agilis*
Pacific kangaroo rat

CRICETIDAE - NEW WORLD RATS AND MICE

- Reithrodontomys megalotis*
western harvest mouse
- Peromyscus boylii*
brush mouse
- Peromyscus californicus*
California mouse
- Peromyscus eremicus*
cactus mouse
- + *Peromyscus maniculatus*
deer mouse
- Peromyscus truei*
pinyon mouse
- Onychomys torridus*
southern grasshopper mouse
- Neotoma lepida intermedia*
desert woodrat
- + *Neotoma lepida*
desert woodrat
- Neotoma fuscipes*
dusky-footed woodrat

Microtus californicus
California vole

MURIDAE - OLD WORLD MICE, RATS, AND VOLES

- * *Rattus rattus*
black rat
- * *Mus musculus*
house mouse

CANIDAE - WOLVES & FOXES

- * *Canis familiaris*
domestic dog
- + *Canis latrans*
coyote
- Urocyon cinereoargenteus*
gray fox

PROCYONIDAE - RACCOONS

- Bassariscus astutus*
ringtail
- + *Procyon lotor*
raccoon

MUSTELIDAE - WEASELS, SKUNKS & OTTERS

- Mustela frenata*
long-tailed weasel
- Taxidea taxus*
American badger
- Spilogale gracilis*
western spotted skunk
- + *Mephitis mephitis*
striped skunk

FELIDAE - CATS

- * *Felis catus*
domestic cat
- Felis concolor*
mountain lion

Lynx rufus
bobcat

EQUIDAE - HORSES

+ *Equus* sp.
domestic horse

CERVIDAE - DEER

+ *Odocoileus hemionus*
mule deer

FLORAL COMPENDIUM – CHATSWORTH RIDGE ESTATES

The floral compendium lists species identified on the project site.

* = non-native species

DRYOPTERIDACEAE

Dryopteris arguta
wood fern

POLYPODIACEAE

Polypodium californicum
California polypody

PTERIDACEAE

Aspidotis californica
California lace fern

Adiantum jordanii
California maiden-hair

Pellaea andromedifolia
coffee fern

Pentagramma triangularis ssp. triangularis
goldback fern

SELAGINELLACEAE

Selaginella bigelovii
Bigelow's mossfern

PINACEAE

**Cedrus deodara*
deodar cedar

**Pinus canariensis*
Canary island pine

**Pinus halepensis*
Aleppo pine

ACERACEAE

Acer negundo ssp. *californicum*
box elder

AMARANTHACEAE

**Amaranthus retroflexus*
red root pigweed

ANACARDIACEAE

Malosma laurina
laurel sumac

Rhus ovata
Sugar bush

Rhus trilobata
basket plant

**Schinus molle*
Peruvian pepper tree

Toxicodendron diversilobum
poison oak

APIACEAE

Apiastrum angustifolium
mock parsley

Berula erecta
cut-leaved water parsnip

Lomatium dasycarpus ssp. *dasycarpum*
woolly lomatium

APOCYNACEAE

Nerium oleander
oleander

Vinca major
greater periwinkle

ASCLEPIADACEAE

Asclepias californica
California milkweed

Asclepias fascicularis
narrow-leaf milkweed

ASTERACEAE

Acourtia microcephala
sacapellote

Ambrosia acanthicarpa
sand-bur

Ambrosia psilostacha
western ragweed

Artemisia douglasiana
mugwort

Artemisia dracunculus
tarragon

Artemisia californica
California sagebrush

Baccharis pilularis
coyote bush

Baccharis salicifolia
mulefat

Brickellia californica
California brickellbush

Brickellia nevinnii
Nevin's Brickellia

**Carduus pycnocephalus*
Italian thistle

**Centaurea melitensis*
tocalote

Cirsium occidentale var. *californicum*
California thistle

**Cirsium vulgare*
bull thistle

**Conyza bonariensis*
little horseweed

Conyza canadensis
common horseweed

Encelia californica
bush sunflower

Erigeron foliosus var. *foliosus*
leafy fleabane

Eriophyllum confertiflorum
golden yarrow

Filago californica
herba impia
Filago gallica
narrow-leaved filago
Gazania linearis
gazania
Gnaphalium bicolor
bicolor cudweed
Gnaphalium californicum
California everlasting
Gnaphalium canescens ssp. benolens
fragrant everlasting
**Gnaphalium luteo-album*
weedy cudweed
Gnaphalium paulestre
lowland cudweed
Hazardia squarrosa var. grindeliodes
sawtooth goldenbush
Helianthus gracilentus
slender sunflower
Hemizonia fasciculata
fscicled tarweed
Heterotheca grandiflora
telegraph weed
**Hypocharis glabra*
smooth cat's-ear
**Lactuca serriola*
prickly lettuce
Lessingia filaginifolia var. filaginifolia
California-aster
Malacothrix saxatilis var. tenuifolia
cliff malacothrix
Rafenesquia californica
California chicory
**Senecio vulgaris*
common groundsel
**Silybum marianum*
milk thistle
Solidago californica
California goldenrod
**Sonchus asper*
prickly sow-thistle
**Sonchus oleraceus*
sow-thistle

**Taraxacum officinale*
dandelion

Uropappus lindleyi
silver puffs

Venegasia carpesoides
canyon sunflower

BORAGINACEAE

Amsynckia intermedia
rancher's fiddleneck

Cryptantha intermedia
common cryptantha

Cryptantha micromeres
minute-flower cryptantha

Pectocarya linearis ssp. *ferocula*
slender pectocarya

BRASSICACEAE

**Brassica nigra*
black mustard

**Capsella bursa-pastoris*
shepherd's purse

**Hirshfeldia incana*
short-pod mustard

Lepidium lasiocarpum var. *lasiocarpum*
hairy peppergrass

**Raphanus sativa*
wild radish

Rorippa nasturtium-aquaticum
water cress

**Sisimbryum altissimum*
tumble mustard

**Sisimbryum irio*
London rocket

CACTACEAE

**Opuntia ficus-indica*
Indian fig

Opuntia littoralis
coast prickly-pear

CAPRIFOLIACEAE

- Lonicera hispidula* var. *vacillans*
California honeysuckle
Sambucus mexicana
Mexican elderberry
Symphoricarpos mollis
spreading snowberry

CARYOPHYLLACEAE

- **Silene gallica*
common catchfly
Silene laciniata ssp. *major*
Mexican pink
**Stellaria media*
chickweed

CHENOPODIACEAE

- **Atriplex semibaccata*
Australian saltbush
**Chenopodium album*
white goosefoot
**Chenopodium ambrosioides*
Mexican tea
Chenopodium californicum
California goosefoot
**Chenopodium rubrum*
alkali goosefoot
**Salsola tragus*
Russian thistle

CISTACEAE

- Helianthemum scoparium*
California rock-rose

CONVOLVULACEAE

- Calystegia macrostegia*
wild morning-glory
**Convolvulus arvensis*
bindweed

CRASSULACAE

- Crassula connata*
pigmy stonecrop
Dudleya lanceolata
coastal dudleya
Dudleya pulverulenta
chalk lettuce

CUCURBITACEAE

- Cucurbita foetidissima*
calabazilla
Marah macrocarpus var. *macrocarpus*
wild cucumber

CUSCUTACEAE

- Cuscuta californica* var. *californica*
dodder

DATISCAEAE

- Datisca glomerata*
durango root

ERICACEAE

- Arctostaphylos glandulosa*
eastwood manzanita

EUPHORBIACEAE

- Chamaesyce albomarginata*
rattlesnake weed
Croton californicus
croton
Eremocarpus setiger
doveweed
**Euphorbia peplus*
petty spurge
**Ricinus communis*
castor bean

FABACEAE

- Astragalus trichopodus*
southern California locoweed
- Lathyrus vestitus*
wild sweet-pea
- Lotus purshianus* var. *purshianus*
Spanish clover
- Lotus scoparius*
deerweed
- Lotus strigosus*
strigose lotus
- Lupinus albifrons* var. *albifrons*
silver bush lupine
- Lupinus bicolor*
dove lupine
- Lupinus hirsutissimus*
stinging lupine
- Lupinus truncatus*
collar lupine
- Melilotus alba*
white sweetclover
- **Melilotus indica*
sourclover
- **Medicago polymorpha*
California burclover
- **Spatium junceum*
Spanish broom
- Trifolium gracilentum* var. *gracilentum*
pin-point clover

FAGACEAE

- Quercus agrifolia*
coast live oak
- Quercus berberidifolia*
California scrub oak

GERANIACEAE

- **Erodium cicutarium*
red-stemmed filaree

- **Erodium botrys*
long-beaked filaree
**Erodium moschatum*
white-stemmed filaree
Geranium carolinianum
Carolina geranium

GROSSULARIACEAE

- Ribes malvaceum* var. *viridifolium*
chaparral currant

HYDROPHYLLACEAE

- Emmananthe penduliflora*
whispering bells
Eriodictyon crassifolium var. *crassifolium*
thick-leaved yerba santa
Eucrypta chrysanthemifolia var. *chrysanthemifolia*
eucrypta
Phacelia cicutaria var. *hispida*
caterpillar phacelia
Phacelia distans
common phacelia
Phacelia parryi
Parry's phacelia
Phacelia ramosissima
branching phacelia
Pholistoma aurium var. *auritum*
fiesta flower

JUGLANDACEAE

- Juglans californica* var. *californica*
southern California black walnut

LAMIACEAE

- **Lamium amplexicaule*
common henbit
**Marrubium vulgare*
Horehound
**Mentha piperita*
peppermint

Salvia apiana

white sage

Salvia columbariae

chia

Salvia mellifera

black sage

Scutellaria tuberosa

Danny's skullcap

Stachys albens

white hedge nettle

MALVACEAE

Malacothamnus fasciculatus

mesa bush mallow

**Malva parviflora*

cheeseweed

MORACEAE

**Ficus carica*

edible fig

MYRTACEAE

**Eucalyptus camaldulensis*

river red gum

**Eucalyptus globulus*

blue gum

**Eucalyptus polyanthemos*

silver dollar gum

NYCTAGINACEAE

Mirabilis californica

wishbone bush

OLEACEAE

Fraxinus dipetala

California ash

**Olea europea*

olive

ONAGRACEAE

Camissonia bistorta
southern suncup

Camissonia californica
false mustard

Clarkia unguiculata
elegant clarkia

Epilobium canum
California fuchsia

Epilobium ciliatum
green willow-herb

OXALIDACEAE

**Oxalis pes-caprae*
bermuda buttercup

PAEONACEAE

Paeonia californica
California peony

PLANTAGINACEAE

**Plantago lanceolata*
lance-leaved plantain

Plantago major
common plantain

PLANTANACEAE

Platanus racemosa
western sycamore

POLEMONIACEAE

Leptodactyon californicum
prickley phlox

Navarretia hamata
southern hooked navarretia

POLYGONACEAE

Chorizanthe staticoides
Turkish rugging
Eriogonum elongatum
tall buckwheat
Eriogonum fasciculatum var. *foliolosum*
California buckwheat

Eriogonum gracile
slender eriogonum
Lastarriaea coriacea
lastarriaea
**Polygonum arenastrum*
common knotweed
Pterostegia drymarioides
granny's hairnet
Rumex conglomeratus
whorled dock
**Rumex crispus*
curly dock

PORTULACAECAE

Claytonia perfoliata ssp. *perfoliata*
miner's lettuce

PRIMULACEAE

**Anagallis arvensis*
scarlet pimpernel

RANUNCULACEAE

Clematis ligusticifolia
virgin's bower
Delphinium cardinale
scarlet larkspur

RHAMNACEAE

Ceanothus crassifolius
hoary-leaved ceanothus

Rhamnus ilicifolia
holly-leaf redberry

ROSACEAE

Adenostoma fasciculatum
chamise
Cercocarpus betuloides
birch-leaf mountain mahogany
Heteromeles arbutifolia
Toyon
Potentilla glandulosa ssp. *glandulosa*
sticky cinquefoil
Rosa californica
California rose
**Rosa* sp.
ornamental rose
**Rubus discolor*
Himalayan blackberry
Rubus ursinus
California blackberry

APPENDIX B

SENSITIVE SPECIES REPORTS

0086
1999
SCANNED

October 7, 1999

Mr. Brad Henderson
Glenn Lukos Associates
23441 South Pointe Drive, Suite 150
Laguna Hills, Ca 92653

Dear Brad:

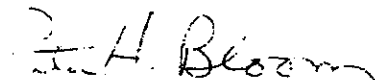

As requested, I have completed two diurnal and two nocturnal U.S. Fish & Wildlife Service protocol surveys for red-legged frogs (*Rana aurora draytonii*) on the proposed Chatsworth Ridge Estates project in Los Angeles County. Surveys were conducted in portions of Devil Canyon and Brown's Canyon

While habitat conditions in both canyons were plausible for red-legged frogs, none were found. Brown's Canyon contains perennial water with adequate shading but it lacked the deeper pools necessary for escape areas, and for tadpoles to safely metamorphose. Although full of mature willows the lower end of Devil Canyon contained less water and also lacked pools of the appropriate depth. Devil Canyon in particular may have supported red-legged frogs but may have disappeared due to the installation of two small dams. Predictably, these dams would have changed sediment deposition and erosional forces significantly. The only anurans found in both streams in relatively small numbers were Pacific tree frogs (*Hyla regilla*).

Surveys were conducted on Aug. 31, Sept. 5, and Sept. 18, 1999. Weather conditions were good with clear skies and maximum daytime temperatures about 85 degrees.

Should you have any questions, please call me at 714-544-6147. Thank you for the opportunity to work with you on this project.

Sincerely,

Peter H. Bloom
Research Biologist

SUBJECT: Submittal Requirements of Coastal California Gnatcatcher Surveys on Chatsworth Ridge Estates, Chatsworth, Los Angeles County, California.

Dear Mr. Waln:

This letter report summarizes the methodology and findings of surveys for the federally-listed threatened coastal California gnatcatcher (*Polioptila californica californica*) conducted by Glenn Lukos Associates, Inc. (GLA) in Los Angeles County, California. GLA was retained by Chatsworth Ridge Estates to determine the presence or absence of the coastal California gnatcatcher on the Chatsworth Ridge Estates project site.

SURVEY LOCATION

The Chatsworth Ridge Estates project site is located in northwestern Los Angeles County within the City of Chatsworth. The project site is located north of the 118 Freeway, east of Topanga Canyon, west of De Soto, and south of Oat Mountain. The project is depicted on the U.S. Geological Survey (USGS) 7.5 minute topographic map Oat Mountain, California (dated 1952 and photorevised 1969)[Exhibit 1]. The project covers an area of approximately 238.9 acres of which approximately 5 acres consist of coastal sage scrub and adjacent chaparral areas. Elevation on the project site ranges from 1200 to 1718 feet above sea level. All areas of coastal sage scrub and other habitats within a 100-foot radius were surveyed for the coastal California gnatcatcher.

PLANT COMMUNITIES

Plant communities within the project area included chaparral, coastal sage scrub (CSS), riparian woodland, eucalyptus, and oak woodland. The CSS onsite is of low quality and does not provide adequate nesting opportunities for the gnatcatcher. The coastal sage scrub occurs in a previously graded area near the middle of the site, and may represent an early-successional vegetation association. The CSS patches are small in size and are

surrounded by either dense chamise chaparral or non-native grassland. Dominant plant species present within the coastal sage scrub included: California sagebrush (*Artemisia californica*), deerweed (*Lotus scoparius*), and black sage (*Salvia mellifera*). Other species found within the CSS included slender wild oats (*Avena barbata*), saw-toothed goldenbush (*Hazardia squarrosa*), and valley lessingia (*Lessingia glandulifera* var. *glandulifera*).

METHODOLOGY

Surveys for the coastal California gnatcatcher were conducted according to the guidelines issued by the U.S. Fish and Wildlife Service (1997). These guidelines stipulate that six visits be conducted within areas of suitable habitat, with at least seven days between site visits. Field surveys were performed by GLA biologist Amy L. Leverett (PRT-818321). Ms. Leverett was assisted by GLA biologist Bradley J. Henderson.

Surveys were conducted on March 30, April 6, 13, 20, 27, and May 4, 1998. The surveys covered all areas of coastal sage scrub as well as adjacent chaparral within the survey area. All areas were covered on foot by walking slowly and methodically along pre-determined transect routes. The location of each transect was based on vegetation and topographic conditions. The presence/absence of coastal California gnatcatchers was determined by identifying all birds by sight and call, then using a combination of taped California gnatcatcher vocalizations and "pishing" sounds. Taped vocalizations were played at intervals of approximately 200 feet or as needed, depending on the vegetation and topography in each area. Sensitive species sightings were recorded and mapped on 1 inch = 80 feet aerial photograph and then transferred to a 1 inch = 80 feet scale topographic map [Exhibit 2]. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 6:45 a.m. to 12:00 p.m. Temperatures ranged from approximately 66 degrees Fahrenheit to 68 degrees Fahrenheit. Wind speeds ranged from 0-20 miles per hour during the surveys, averaging 3-7 miles per hour over the survey period.

RESULTS

During the surveys, no coastal California gnatcatchers were observed. Other birds commonly seen included California quail (*Callipepla californica*), rufous-crowned sparrow (*Aimophila ruficeps*), California towhee (*Pipilo crissalis*), spotted towhee (*Pipilo macularus*), wrentit (*Chamaea fasciata*), western scrub-jay (*Aphelocoma californica*), California thrasher (*Toxostoma redivivum*), blue-gray gnatcatcher (*Polioptila caerulea*), and mourning dove (*Zenaida macroura*).

SUBJECT: Submittal Requirements of Coastal California Gnatcatcher Surveys on Chatsworth Ridge Estates, Los Angeles County, California.

Dear Sir or Madam:

This letter report summarizes the methodology and findings of surveys for the federally-listed threatened coastal California gnatcatcher (*Polioptila californica californica*) conducted by Glenn Lukos Associates, Inc. (GLA) in Los Angeles County, California. GLA was retained by Chatsworth Ridge Estates to determine the presence or absence of the coastal California gnatcatcher on the Chatsworth Ridge Estates project site. Protocol Surveys were originally conducted in 1998, with no observations of the species. The results of the surveys were documented in a letter dated June 4, 1998 to Kirk Waln of the Ventura Field Office. The protocol surveys were repeated in 2000 to update information regarding the potential for the gnatcatcher to utilize the site.

I. SURVEY LOCATION

The Chatsworth Ridge Estates site is located in an unincorporated section of Los Angeles County [Exhibit 1], comprises approximately 238 acres and contains two blue-line drainages, Devil Canyon and Browns Canyon. The site is depicted on the U.S. Geological Survey (USGS) topographic map Oat Mountain, California [dated 1952 and photorevised in 1969] [Exhibit 2]. The site is bounded on the west by Topanga Canyon Boulevard, the north by open space, on the east by Brown's Canyon Road, and the south by the 118 Freeway. The topography of the approximately 238-acre site ranges from relatively flat terrain to extremely steep slopes above the deeper canyons. The elevation of the site ranges from 1200 feet above mean sea level (MSL) to 1,560 feet above MSL. Portions of the property were previously developed as homes and equestrian facilities.

Vegetation Associations

Seven vegetation associations (including ecotonal areas¹) were identified within the project site. Vegetation communities identified include chamise chaparral, coastal sage scrub, coast live oak woodland, and willow woodland. Non-native vegetation communities include non-native grasslands and eucalyptus groves. The acreage for each vegetation association is provided in Table 1. Approximately 13.13 acres of the site have been previously graded or developed and support ruderal non-native species.

Table 1
Vegetation Associations

Vegetation Association	Total Acres
Chamise Chaparral	197.12
Coastal Sage Scrub/Non-Native Grassland	2.36
Coast Live Oak Woodland	7.97
Willow Woodland	9.72
Non-Native Grassland	2.10
Non-Native Grassland/Developed	5.38
Eucalyptus Grove	0.22
Previously Graded or Developed	13.13
Total	238.0 ²

Chamise Chaparral

Chamise (*Adenostoma fasciculatum*) and black sage (*Salvia mellifera*) are the dominant shrubs in this association. Other shrubs include blue elderberry (*Sambucus mexicana*), laurel sumac (*Malosma laurina*), Our Lord's candle (*Yucca whipplei*), California buckwheat (*Eriogonum fasciculatum*) and deerweed (*Lotus scoparius*). The understory is composed of annuals including non-native tocolote (*Centaurea melitensis*), common cryptantha (*Cryptantha intermedia*), various suncups (*Camissonia* spp.), common catchfly (*Silene gallica*), and various non-native grasses. Chamise chaparral occupies flat areas and slopes throughout most of the site, and is the predominant vegetation association observed at the Chatsworth Ridge Estates site. A total of approximately 197.12 acres of chamise chaparral has been identified on the site.

¹ Ecotonal areas are characterized by a blending of two or more distinct vegetation types.

² The 238-acre total includes approximately 15.5 acres of land recently deeded to the Santa Monica Mountains Conservancy in Devil Canyon and Browns Canyon.

Coastal Sage Scrub/Non-Native Grassland Ecotone

The coastal sage scrub on the Chatsworth Ridge Estates site is dominated by California sagebrush (*Artemisia californica*), deerweed (*Lotus scoparius*), and California buckwheat (*Eriogonum fasciculatum*). Other species found within or adjacent to the CSS included California aster (*Lessingia filaginifolia*), slender wild oats (*Avena barbata*), saw-toothed goldenbush (*Hazardia squarrosa*), black sage (*Salvia mellifera*) and chamise (*Adenostoma fasciculatum*).

The coastal sage scrub onsite occurs in a previously graded homestead near the middle of the site, and most likely represents a transitional early-successional vegetation association. It is likely that this area would gradually be replaced by chaparral species if left undisturbed as observed in many areas throughout the state (Mooney 1977)³. The total area of coastal sage scrub/non-native grassland identified on the site is approximately 2.36 acres.

Coast Live Oak Woodland

The dominant overstory species within this association is coast live oak (*Quercus agrifolia*). The understory includes shrubs such as toyon (*Heteromeles arbutifolia*), southern California black walnut, blue elderberry, poison oak, and non-native grasses. Coast live oak woodland onsite was most often observed adjacent to drainages, or on shaded, north-facing slopes. The total area of oak woodland identified onsite is approximately 7.97 acres. However, individual oak trees are found in most of the other vegetation associations on the site.

Willow Woodland

Dominant vegetation within this association includes arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), mulefat (*Baccharis salicifolia*), and Fremont's cottonwood (*Populus fremontii*). Less common overstory species include black cottonwood (*Populus balsamifera* ssp. *trichocarpa*), western sycamore (*Platanus racemosa*), Southern California Black Walnut (*Juglans californica* var. *californica*) and occasional box elder (*Acer negundo* var. *californicum*). Adjacent mesic areas support scattered stands of coast live oak (*Quercus agrifolia*). The understory includes California blackberry (*Rubus ursinus*), poison oak (*Toxicodendron diversilobum*), and mugwort (*Artemisia douglasiana*). This association occurs in areas adjacent to the Browns Canyon and Devil Canyon drainages, characterized by areas of dense trees as well

³ Mooney, Harold A. 1977. *Southern Coastal Scrub*. Terrestrial Vegetation of California. California Native Plant Society, University of California, Davis.

as more shrubby willow and mule fat in areas prone to stream scouring. The total area of willow woodland identified on the site is approximately 9.72 acres.

Non-Native Grassland

Non-native grassland on-site is dominated by slender wild oats, ripgut brome (*Bromus diandrus*), Black mustard (*Brassica nigra*), summer mustard (*Hirschfeldia incana*), common catchfly (*Silene gallica*), and tocolote (*Centaurea melitenis*). The non-native grassland identified on the site occupies approximately 2.10 acres and primarily occurs in areas of past disturbance. Areas surrounding previously developed homes are also dominated by non-native grassland and total approximately 5.38 acres.

Eucalyptus Grove

Scattered non-native eucalyptus trees are found in flat areas throughout the site and seedlings have begun to colonize riparian areas. A grove of mature blue gum (*Eucalyptus globulus*) and red gum (*Eucalyptus camaldulensis*) has been planted near Devil Canyon, presumably for fuel wood production. The total area of eucalyptus grove identified on the site is approximately 0.22 acre. This vegetation association includes an understory typically composed of weedy annual grasses and herbs. Scattered eucalyptus trees occupy most other vegetation associations in several locations.

Previously Developed/Graded Areas

Previously developed areas have been graded or repeatedly cleared of vegetation. Some areas exhibit a cover of bare earth and rocks, while other areas are dominated by ruderal plant species, many of them non-native. Summer mustard (*Hirschfeldia incana*), slender wild oat (*Avena barbata*), storksbill (*Erodium* spp.), and cheeseweed (*Malva parviflora*) are common non-natives colonizing these disturbed areas. Previously developed areas total 13.13 acres.

II. METHODOLOGY

Surveys for the coastal California gnatcatcher were conducted according to the guidelines issued by the U.S. Fish and Wildlife Service (1997). These guidelines stipulate that six visits be conducted within areas of suitable habitat, with at least seven days between site visits. Field surveys were performed by GLA biologist Bradley Henderson (TE-020025-0).

Surveys were conducted on May 12, 19, 26, June 6, 13, and 22, 2000. The surveys covered all areas of coastal sage scrub as well as adjacent chaparral within the approximately five-acre survey area. All areas were covered on foot by walking slowly and methodically along pre-

determined transect routes. The location of each transect was based on existing roads and horse trails that bisect the CSS and allow unobstructed views.

The presence/absence of coastal California gnatcatchers was determined by identifying all birds by sight and call, then using a combination of taped California gnatcatcher vocalizations and "pishing" sounds. Taped vocalizations were played at intervals of approximately 200 feet or as needed, depending on the vegetation and topography in each area. Sensitive species sightings were recorded and mapped on 1 inch = 80 feet aerial photograph and then transferred to a 1 inch = 100 feet scale topographic map [Exhibit 2]. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 7:05 a.m. to 11:15 am. Temperatures ranged from approximately 57 degrees Fahrenheit to 75 degrees Fahrenheit. Wind speeds ranged from 0-7 miles per hour during the surveys. Table 2 summarizes survey times, temperature, and weather conditions.

Table 2
Summary of survey conditions

Date	Start Time	End Time	Temperature (F, start/end)	Windspeed (mi/hr)	Cloud Cover (% , start/end)
5/12	0705	0840	57/61	0-2 W	100/100 low clouds
5/19	0830	0955	62/64	2-4 N	0/0
5/26	0715	0830	63/65	0	85/25 low clouds
6/2	1000	1115	68/75	2-7 W	0
6/13	0730	0820	71/74	0	0
6/20	0730	0817	62/66	0-2 W	20/0 low clouds

III. RESULTS

During the surveys, no coastal California gnatcatchers or brown-headed cowbirds were observed. Birds that were commonly identified include California quail (*Callipepla californica*), California towhee (*Pipilo crissalis*), spotted towhee (*Pipilo macularus*), wrenit (*Chamaea fasciata*), western scrub-jay (*Aphelocoma californica*), California thrasher (*Toxostoma redivivum*), phainopepla (*Phainopepla nitens*), northern mockingbird (*Mimus polyglottos*), Bullock's oriole (*Icterus galbula*), bushtit (*Psaltiriparus minimus*), lesser goldfinch (*Carduelis psaltria*), and mourning dove (*Zenaida macroura*).

U.S. Fish and Wildlife Service
August 3, 2000
Page 6

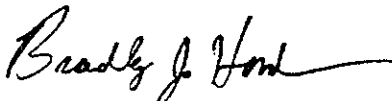

IV. CONCLUSION

The CSS is of low quality and does not likely provide adequate nesting opportunities for the gnatcatcher. The coastal sage scrub occurs in a previously graded area near the middle of the site, and represents an early-successional vegetation association repeatedly disturbed by construction and fires. The CSS patches are small in size and are surrounded by either dense chamise chaparral or non-native grassland. While it is possible that gnatcatchers could use the site for foraging or dispersal, this behavior is unlikely given the lack of breeding habitat and known gnatcatcher occurrences in the area.

Should you have any questions regarding the methodology or findings of this report, please do not hesitate to call me at (949) 837-0404.

Sincerely,

SUBJECT: Submittal Requirements of Least Bell's Vireo Surveys on Chatsworth Ridge Estates, Chatsworth, Los Angeles County, California.

Dear Mr. Waln:

This letter report summarizes the methodology and findings of surveys for the federally-listed endangered least Bell's vireo (*Vireo bellii pusillus*) conducted by Glenn Lukos Associates, Inc. (GLA) in Los Angeles County, California. GLA was retained by Chatsworth Ridge Estates to determine the presence or absence of the least Bell's vireo on the Chatsworth Ridge Estates project site.

SURVEY LOCATION

The Chatsworth Ridge Estates project site is located in northwestern Los Angeles County adjacent to the City of Chatsworth. The project site is located north of the 118 Freeway, east of Topanga Canyon, west of De Soto, and south of Oat Mountain. The project is depicted on the U.S. Geological Survey (USGS) 7.5 minute topographic map Oat Mountain, California (dated 1952 and photorevised 1969)[Exhibit 1]. The project covers an area of approximately 238.9 acres of which approximately 17 acres consist of willow riparian areas. Elevation on the project site ranges from 1200 to 1718 feet above sea level. All areas of willow riparian woodland habitat located within the boundaries of the project site were surveyed for the least Bell's vireo [Exhibit 2].

PLANT COMMUNITIES

Plant communities within the project area included chaparral, coastal sage scrub (CSS), willow riparian woodland, eucalyptus, and oak woodland. The willow riparian woodland onsite is of high quality and provides adequate nesting and foraging opportunities for the vireo. The willow riparian woodland is dominated by arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), narrow-leaved willow (*Salix exigua*), western sycamore

(*Platanus racemosa*), Fremont cottonwood (*Populus fremontii*), coast live oak (*Quercus agrifolia*), and mule fat (*Baccharis salicifolia*). Other species occurring within this habitat include Mexican elderberry (*Sambucus mexicana*), poison oak (*Toxicodendron diversilobum*), mugwort (*Artemisia douglasiana*), and California blackberry (*Rubus ursinus*).

METHODOLOGY

Surveys for the least Bell's vireo were conducted according to the guidelines issued by the U.S. Fish and Wildlife Service (1992). These guidelines stipulate that eight visits be conducted within areas of suitable habitat, with at least seven days between site visits between April 1 and July 31. Field surveys were performed by GLA biologist Amy L. Leverett-Henderson under appropriate weather conditions. Ms. Leverett-Henderson was assisted by GLA biologist Bradley J. Henderson.

Surveys were conducted on June 8, 15, 22, 29, July 6, 13, 20, and 27, 1998. The surveys covered all areas of willow riparian woodland located within the boundaries of the project site. All areas were covered on foot by walking slowly and methodically along the drainage. The presence/absence of least Bell's vireo was determined by identifying all birds by sight and call. No taped least Bell's vireo vocalizations were used. Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from 5:30 a.m. to 11:00 a.m. Temperatures ranged from approximately 56 degrees Fahrenheit to 70 degrees Fahrenheit. Wind speeds ranged from 0-5 miles per hour during the surveys, averaging 0-2 miles per hour over the survey period.

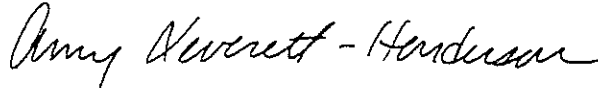

RESULTS

During the surveys, no least Bell's vireo were observed. Other birds commonly seen included California quail (*Callipepla californica*), California towhee (*Pipilo crissalis*), spotted towhee (*Pipilo erythrophthalmus*), wrentit (*Chamaea fasciata*), western scrub-jay (*Aphelocoma coerulescens*), California thrasher (*Toxostoma redivivum*), Bewick's wren (*Thryomanes bewickii*), Hutton's vireo (*Vireo huttonii*), song sparrow (*Melospiza melodia*), lesser goldfinch (*Carduelis psaltria*), Cooper's hawk (*Accipiter cooperii*), Northern oriole (*Icterus galbula*), Northern flicker (*Colaptes auratus*), Costa's hummingbird (*Calypte costae*), phainopepla (*Phainopepla nitens*), bushtit (*Psaltriparus minimus*), black phoebe (*Sayornis nigricans*), Nuttall's woodpecker (*Picoides nuttallii*) and mourning dove (*Zenaida macroura*).

SUBJECT: Results of Protocol Surveys conducted for the Least Bell's Vireo on the Chatsworth Ridge Estates Project Site, Los Angeles County, California.

Dear Mr. Garlinghouse:

This letter report summarizes the methodology and findings of surveys for the federally-listed endangered least Bell's vireo (*Vireo bellii pusillus*) conducted by Glenn Lukos Associates, Inc. (GLA) for the above-mentioned site in Los Angeles County, California.

INTRODUCTION

The least Bell's vireo is a small, gray, migratory songbird which inhabits riparian habitats of nine southern California counties. The breeding season generally extends from April 10 through July 31. Decreases in populations of least Bell's vireo have been attributed to habitat degradation/destruction and cowbird parasitism. *Vireo bellii pusillus* was officially designated as a state-endangered species on October 2, 1980 and achieved federally-endangered status on May 2, 1986.

SURVEY LOCATION

The Chatsworth Ridge Estates project in Los Angeles County, [Exhibit 1], comprises approximately 222.5 acres and is depicted on the U.S. Geological Survey (USGS) 7.5 minute topographic map Oat Mountain, California (dated 1952 and photo revised in 1969) [Exhibit 2]. The proposed project site is located in an unincorporated section of Los Angeles County near the City of Chatsworth. The topography of the 222.5-acre site consists of north-south ridges,

canyons, and a relatively flat mesa characterized by dry washes and sandstone rock outcrops. The elevation of the site ranges from approximately 1,200 feet above mean sea level (MSL) in the southeastern section to approximately 1,560 feet above MSL in the northern section.

PLANT COMMUNITIES

Plant communities within the survey area included southern willow riparian woodland and oak woodland. The southern willow riparian woodland is of moderate to high quality, providing potential suitable nesting and foraging opportunities for least Bell's vireo.

Dominant vegetation within this association includes arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), mulefat (*Baccharis salicifolia*), and Fremont's cottonwood (*Populus fremontii*). Less common overstory species include black cottonwood (*Populus balsamifera ssp. trichocarpa*), western sycamore (*Platanus racemosa*), southern California black walnut (*Juglans californica var. californica*) and occasional box elder (*Acer negundo var. californicum*). Adjacent mesic areas support scattered stands of coast live oak (*Quercus agrifolia*). The understory includes California blackberry (*Rubus ursinus*), poison oak (*Toxicodendron diversilobum*), and mugwort (*Artemisia douglasiana*). This association occurs in areas adjacent to the Browns Canyon and Devil Canyon drainages, characterized by areas of dense trees as well as more shrubby willow and mule fat in areas prone to stream scouring. The total area of willow woodland identified on the site is approximately 9.72 acres. Much of the southern willow riparian habitat exhibits multi-layered structure with locally dense understory typically associated with least Bell's vireo habitat. Other areas are dominated by large riparian trees with a heavy canopy resulting in little understory due to heavy shading.

METHODOLOGY

Focused surveys for the least Bell's vireo were conducted by GLA biologists Brad Henderson and Jeff Ahrens according to the guidelines issued by the U.S. Fish and Wildlife Service¹. These guidelines stipulate that a minimum of eight visits be conducted within areas of suitable habitat, with at least ten days between site visits.

¹ U.S. Fish and Wildlife guidelines for least Bell's vireo surveys recommend surveys of up to 50 hectares (approximately 120 acres) and no more than 3 linear kilometers (approximately 1.8 miles) per day, depending on site conditions (e.g., density and width of vegetation). U.S. Department of the Interior, Fish and Wildlife Service. 1999. Least Bell's Vireo Survey Guidelines, Published guidelines by Ecological Services Carlsbad Fish and Wildlife Office, 3 pages.

Protocol surveys were conducted on May 2, 12, 22, June 2, 13, 23, July 3, 13, and August 5, 2000.² The surveys covered all areas of mulefat scrub, southern willow scrub, and sycamore woodland. All surveys were begun within an hour of sunrise and completed before 11:00 A.M., in accordance with USFWS guidelines. All suitable areas were covered on foot by walking slowly and methodically through the riparian habitat. The presence/absence of least Bell's vireos was determined by identifying all birds by sight and call, aided by the use of binoculars. No taped vocalizations were used to elicit response from the vireos or any other species potentially present.

Weather conditions during the surveys were conducive to a high level of bird activity. Surveys were conducted from sunrise to 11:00 a.m. Temperatures ranged from approximately 51 degrees Fahrenheit to 84 degrees Fahrenheit. Wind speeds ranged from 0-2 miles per hour during the surveys, averaging one mile per hour over the survey period. Table 1 summarizes the survey dates and weather information for each survey date.

Table 1. Least Bell's Vireo Survey and Weather Information

Date	Observer*	Time (Hrs)	Temperature (°F)	Wind Speed (Mph)	Comments
05/02/00	BH	0711-1050	59-74	No wind	Clear skies
05/12/00	BH	0600-0905	54	2	High cloud cover
05/22/00	BH	0630-0930	57	2	Clear and sunny
06/02/00	BH & JA	0730-1100	64	2	Clear skies
06/13/00	BH & JA	0715-1040	63	0-2	Clear skies
06/23/00	JA	0600-0915	63-84	1-2	Clear skies
07/03/00	JA	0630-0955	59	No wind	Morning overcast
07/13/00	JA	0645-1025	51	0-1	Clear skies
08/05/00	JA	0700-1040	65	No wind	Clear skies

*BH refers to Brad Henderson. JA refers to Jeff Ahrens.

² Least Bell's vireo surveys were previously conducted for the Chatsworth Estates project on June 8, 15, 22, 29, July 6, 13, 20, and 27, 1998 by GLA biologist Amy Henderson. A letter report to Kirk Wain of the USFWS dated August 24, 1998 documents the results of the protocol least Bell's vireo surveys. The least Bell's vireo was not observed on the site during protocol surveys or at any other time during field work.

Mr. Richard Garlinghouse
Presidio Chatsworth Partners LLC
September 21, 2000
Page 4

RESULTS

Least Bell's vireo was not detected on the site. Birds commonly observed within willow riparian woodland included: song sparrow (*Melospiza melodia*), house wren (*Troglodytes aedon*), lesser goldfinch (*Carduelis psaltria*), Nuttall's woodpecker (*Picoides nuttallii*), Pacific-slope flycatcher (*Empidonax difficilis*), Hutton's vireo (*Vireo huttoni*), California towhee (*Pipilo crissalis*), bushtit (*Psaltriparus minimus*), and western scrub-jay (*Aphelocoma californica*).

A complete list of birds identified on the site is attached as Appendix A.

Should you have any questions regarding the methodology or findings of this report, please call me at (949) 837-0404.

Sincerely,

Bradley J. Henderson
Biologist

APPENDIX A
BIRDS OBSERVED DURING LEAST BELL'S VIREO SURVEYS

ACCIPITRIDAE - HAWKS

- Accipiter cooperii*
Cooper's hawk
- Buteo jamaicensis*
red-tailed hawk
- Buteo lineatus*
red-shouldered hawk

FALCONIDAE - FALCONS

- Falco sparverius*
American kestrel

PHASIANIDAE - PHEASANTS & QUAILS

- Callipepla californica*
California quail

COLUMBIDAE - PIGEONS & DOVES

- Zenaida macroura*
mourning dove
- Columbia livia*
rock dove

TROCHILIDAE - HUMMINGBIRDS

- Calypte anna*
Anna's hummingbird
- Archilochus alexandri*
black-chinned hummingbird
- Selasphorus sasin*
Allen's hummingbird

PICIDAE - WOODPECKERS

- Melanerpes formicivorus*
acorn woodpecker
- Picoides nuttallii*
Nuttall's woodpecker
- Picoides pubescens*
downy woodpecker
- Colaptes auratus*

northern flicker

TYRANNIDAE - TYRANT FLYCATCHERS

Contopus sordidulus
western wood-pewee
Empidonax difficilis
Pacific-slope flycatcher
Sayornis nigricans
black phoebe
Myiarchus cinerascens
ash-throated flycatcher

APODIDAE - SWIFTS

Aeronautes saxatalis
white-throated swift

HIRUNDINIDAE - SWALLOWS

Stelgidopteryx serripennis
northern rough-winged swallow
Hirundo pyrrhonota
cliff swallow

CORVIDAE - JAYS & CROWS

Aphelocoma coerulescens
western scrub-jay
Corvus brachyrhynchos
American crow
Corvus corax
common raven

PARIDAE - TITMICE

Baeolophus inornatus
oak titmouse

SITTIDAE - NUTHATCHES

Sitta carolinensis
white-breasted nuthatch

AEGITHALIDAE - BUSHTITS

Psaltriparus minimus
bushtit

TROGLODYTIDAE - WRENS

Thryomanes bewickii

Bewick's wren

Troglodytes aedon

house wren

MUSCICAPIDAE - KINGLETS, GNATCATCHERS, THRUSHES & BABBLERS

Chamaea fasciata

wren-tit

MIMIDAE - THRASHERS

Mimus polyglottos

northern mockingbird

Toxostoma redivivum

California thrasher

PTILOGONATIDAE - SILKY-FLYCATCHERS

Phainopepla nitens

phainopepla

VIREONIDAE - VIREOS

Vireo huttoni

Hutton's vireo

Vireo cassinii

Cassin's vireo

EMBERIZIDAE - WOOD WARBLERS, TANAGERS, BUNTINGS & BLACKBIRDS

Wilsonia pusilla

Wilson's warbler

Pheucticus melanocephalus

black-headed grosbeak

Piranga ludoviciana

western tanager

Pipilo crissalis

California towhee

Pipilo erythrophthalmus

spotted towhee

Melospiza melodia

song sparrow

Spizella atrogularis

black-chinned sparrow

Icterus galbula
Bullock's oriole

FRINGILLIDAE - FINCHES

Carpodacus mexicanus
house finch
Carduelis tristis
American goldfinch
Carduelis psaltria
lesser goldfinch
Carduelis lawrencei
Lawrence's goldfinch

1.0 INTRODUCTION

This report presents methods and results of a focused survey for an Endangered species conducted for the Chatsworth Ridge Estates project, Chatsworth, California. A focused survey was performed to determine the presence or absence of Southwestern Willow Flycatcher (*Empidonax traillii extimus*) within project boundaries and a surrounding 30-meter (100-foot) buffer.

The survey area consists of a single approximately 17-acre (6.9-hectare) site located on the project site in the community of Chatsworth in an unincorporated portion of Los Angeles County. This site is at the north end of Canoga Avenue between Topanga Canyon Boulevard and Browns Canyon Road (Figure 1). The site lies on the Oak Mountain, California, 7.5-minute U.S.G.S. quadrangle map and is on page 500, blocks 1A and 1B, of the current Thomas Bros. Guide for Los Angeles County (TBM 1997).

Southwestern Willow Flycatcher was not found on the site, and can be considered absent at this time. If onsite project actions are not completed by July 1999, additional studies would be necessary to confirm that the Southwestern Willow Flycatcher continues to be absent from the project site.

2.0 EXISTING CONDITIONS

The riparian habitat present on the study site consists largely of Willow-cottonwood riparian scrub and woodland, dominated by Red Willow (*Salix laevigata*) and Arroyo Willow (*Salix lasiolepis*), with Southern Mixed Chaparral on the surrounding slopes and extensive Coast Live Oak Woodland-Forest north of the project area. A moderate flow of water was present in the riparian area throughout the survey. Precise elevations were not determined, but appear to be between about 1200 and 1500 feet (365 and 457 meters).

3.0 FOCUSED SURVEY FOR SOUTHWESTERN WILLOW FLYCATCHER

The following sections present the methods, background and results of this focused survey conducted for the Chatsworth Ridge Estates project. This focused survey was conducted to determine the presence or absence of Southwestern Willow Flycatcher (*Empidonax traillii extimus*). Taxonomy and nomenclature for plants follows Hickman (1993), AOU (1998) for birds, and Laudenslayer et al. (1991) for all other terrestrial vertebrates. Habitat classification is based on Holland (1986).

3.1 Methods

From 30 May 1998 through 03 July 1998 a focused survey for Southwestern Willow Flycatcher was conducted in all potential habitat within the proposed project site. Willow Flycatcher is a state listed Endangered species, while the component subspecies breeding in southern California, Southwestern Willow Flycatcher, is a federally listed Endangered species.

All potential habitat on the entire project site was surveyed according to the current survey protocol (see below). Component floral species, their physical structure, and condition were evaluated based on both personal experience with, and published literature on this species' habitat requirements. See the discussion below for survey methods. Habitat structure was not analyzed quantitatively, and no attempt was made to define home ranges or territories. Potential habitat extending at least 30 meters (100 feet) beyond the project site boundaries was also examined to provide context.

The survey was conducted by two biologists: Stephen J. Myers (permit #PRT-804203) and Chet McCaugh (permit # PRT-836517). See Table 1 for dates, times and site conditions.

Table 1: Study Area Visits and Conditions for Southwestern Willow Flycatcher Survey.

Date	Times	Who	Conditions
30 May 98	0600 - 1000	S.J. Myers	46° - 68°F; cloud cover 0%; wind 0-3 mph (S)
20 June 98	0540 - 1030	S.J. Myers	58° - 69°F; cloud cover 100%; wind 0-2 mph (SW)
03 July 98	0615 - 1035	C. McGaugh	cloud cover 100%; wind calm

The published survey methodology (Sogge et al. 1997) was followed. On the three survey visits, all potential habitat was carefully checked for this species; see beginning paragraphs of this Section for general description of field methods. The survey protocol to determine presence or absence of Southwestern Willow Flycatcher requires a federal 10(A)1(a) permit (see above for permit numbers).

This USFWS-adopted protocol includes the following four basic elements: (1) preparation: the surveyor must be familiar with the species' habitats, behavior, and identification; (2) timing: three visits must be made to all potentially occupied habitat, each in a separate window (15 - 31 May; 01 - 21 June; 22 June - 10 July), and with each visit no closer together than at 5-day intervals; (3) methods: at each site surveyors should cautiously and conservatively broadcast recorded vocalizations of Willow Flycatchers; (4) surveys should be limited to the morning period between one hour before sunrise and 1000. Additional details on methods are provided in Sogge et al. (1997). All protocol methods were followed for the surveys conducted on the project site.

3.2 Background

This section presents a general and abbreviated discussion of the status, distribution, and breeding ecology of the species for which presence/absence focused surveys were conducted.

A small bird of muted colors, the Southwestern Willow Flycatcher (*Empidonax traillii extimus*) is an insectivore, taking insects on the wing or gleaning them from foliage. The species as a whole was given protection by the state of California as an Endangered species on 03 December 1990, and the Southwestern subspecies was federally listed as an Endangered species effective 29 March 1995.

This race of the Willow Flycatcher was originally described about 50 years ago (Phillips 1948), but our current understanding of its identification and range is based upon detailed work by Unitt (1987), which indicates that it breeds from western Texas west through southern California, north to southern Utah and southern Nevada, and south into extreme northern Mexico. Within California, it breeds from the south fork of the Kern River near the southern end of the Sierra Nevada, thence eastward from at least Santa Barbara County south to Baja California. The species as a whole is known to breed from near sea level to high mountain meadows, and this subspecies may be no exception in this regard. Winter range and habitats of *E. t. extimus* are almost completely unknown, but the species as a whole is known to winter from southern Mexico south at least to Panama (AOU 1998).

Southwestern Willow Flycatchers are normally present in southern California on breeding grounds beginning in early May and continuing through at least late July, though timing of local birds is obscured by more abundant migrants of other subspecies passing through the area. Migrants of subspecies other than *E. t. extimus* are very widespread, and uncommon to fairly common as they pass through southern California, mainly from late May through mid-June, and again from late July through September. The period in which migrants of other races are absent from southern California is approximately 14 June through 17 July (Unitt 1987).

As noted in the Federal Register final rule listing the species as endangered (USFWS 1995), the Southwestern Willow Flycatcher, "occurs in riparian habitats along rivers, streams, or other wetlands, where dense growths of willows (*Salix* spp.), *Baccharis* spp., Arrowweed (*Phytolacca* spp.), buttonbush (*Cephalanthus* spp.), tamarisk (*Tamarix* spp.) Russian olive (*Elaeagnus* spp.) or other plants are present, often with a scattered overstory of

cottonwood (*Populus* spp.) . . . Throughout the range of *E.t. extimus*, these riparian habitats tend to be rare, widely separated, small and/or linear locales, separated by vast expanses of arid lands. The Southwestern Willow Flycatcher has experienced extensive loss and modification of this habitat and is also endangered by other factors including brood parasitism by the Brown-headed Cowbird."

In describing nesting habitats, the Final Rule (USFWS 1995) also noted that the subspecies, "nests in thickets of trees and shrubs approximately 4 - 7 meters (13 - 23 feet) or more in height, with dense foliage from approximately 0 - 4 meters (13 feet) above ground, and often a high canopy cover percentage. The diversity of nest site plant species may be low (e.g., willows) or comparatively high . . . Nest site vegetation may be even- or uneven-aged, but is usually dense and structurally homogenous . . . Following modern changes in riparian plant communities, *E.t. extimus* still nests in native vegetation where available, but has been known to nest in thickets dominated by tamarisk and Russian olive . . . Nesting Willow Flycatchers of all subspecies generally prefer areas with surface water nearby . . . but *E.t. extimus* virtually always nests near surface water or saturated soil (Phillips et al. 1964, Muiznieks et al. 1994). At some nest sites surface water may be present early in the breeding season but only damp soil is present by late June or early July."

3.3 Results

Southwestern Willow Flycatcher was not found on the site, and can be considered absent at this time. However, the project site has potentially appropriate habitat and could provide habitat in the future for the Southwestern Willow Flycatcher. If onsite project actions are not completed by July 1999, additional studies would be necessary to confirm that the Southwestern Willow Flycatcher continues to be absent from the project site.

Two species of special interest were recorded on the project site during the surveys: Cooper's Hawk (*Accipiter cooperii*; state Species of Special Concern), and Ashy Rufous-crowned Sparrow (*Aimophila ruficeps canescens*, state Species of Special Concern). A single Cooper's Hawk was observed on 20 June, in addition to 3 juveniles and at least one adult seen on 03 July. A pair of Rufous-crowned Sparrows were observed on 30 May, and 6 individuals, including a juvenile, were noted on 20 June. No other legally sensitive or special interest species were recorded.

4.0 CONCLUSIONS

A focused survey was conducted for Southwestern Willow Flycatcher on a 17-acre (6.9-hectare) site in an unincorporated area of Los Angeles County for the Chatsworth Ridge Estates project. Southwestern Willow Flycatcher is a state and federally listed Endangered bird species breeding across the southwestern United States from southern California east to western Texas. Surveys were conducted in accordance with the current presence/absence survey protocol, by biologists qualified and holding current permits for such work. Southwestern Willow Flycatcher was confirmed to be absent at this time. Should project actions be delayed for more than one year after this survey was conducted (i.e., after July 1999), it will be necessary to re-confirm the status of this species on the project site.

Please note that this report is not intended as a general analysis of biological issues on the site, and is not intended to provide interpretations of significance in light of the California Environmental Quality Act or other environmental regulations at local, state or federal levels.

1.0 INTRODUCTION

This report presents information on a focused survey to determine presence or absence of Southwestern Willow Flycatcher (*Empidonax traillii extimus*) on a 17-acre (6.9-hectare) project site in an unincorporated area of Los Angeles County, California. The survey was conducted along reaches of Browns Canyon and Devil Canyon which lie within the project site; these two reaches are hereafter referred to as the, "survey area."

The survey area lies just within and immediately north of the community of Chatsworth in the City of Los Angeles; the areas outside the city are in unincorporated portions of Los Angeles County (Figure 1). The Browns Canyon reach is shown on page 500 (block B1) and page 480 (block B7) of the current Thomas Guide for Los Angeles County (Thomas Bros. 2000), while the Devil Canyon reach is shown on page 500 (blocks A1 and B1). Both reaches are also shown on the Oat Mountain, California, 7.5-minute U.S.G.S. quadrangle map (Oat Mountain 1992). The survey area consists of approximately 7050 linear feet of riparian habitat with an estimated average width of just under 50 feet, or a total of approximately 8 acres (about 3.1 hectares) of Willow Flycatcher potential habitat (Exhibit 1).

2.0 EXISTING CONDITIONS

For this report taxonomy and nomenclature follow Hickman (1993) for plants, AOU (1998) for birds species, Unitt (1987) and Browning (1993) for Willow Flycatcher subspecies taxonomy and distribution, and Laudenslayer et al. (1991) for non-avian terrestrial vertebrates. Natural community terminology generally follows Holland (1986).

The area of the focused survey consists of rolling foothills at the base of the Santa Susana Mountains of eastern Los Angeles County (Exhibit 1). Surrounding canyon slopes throughout the area support intact Southern Mixed Chaparral, with small numbers of scattered rural residences. Elevation within the study area along Devil Canyon ranges between approximately 1120 and 1230 feet (241 to 375 meters), and along Browns Canyon between approximately 1165 and 1230 feet (355 to 375 meters) above sea level. Overall, bank width varies between approximately 10 and 40 feet (3 to 12 meters), with potential habitat width estimated at 10 to approximately 100 feet (3 to 24 meters), though the average width is probably between 40 and 50 feet.

The Browns Canyon reach supports primarily Southern Cottonwood - Willow Riparian Forest, variably dominated by Red Willow (*Salix laevigata*), Arroyo Willow (*Salix lasiolepis*), and Coast Live Oak (*Quercus agrifolia*), with smaller amounts of Western Sycamore (*Platanus racemosa*). The understory in this reach is dominated by Mule Fat (*Baccharis salicifolia*) and sapling willows, with an herb layer dominated by California Mugwort (*Artemisia douglasiana*) and Western Ragweed (*Ambrosia psilostachya*) and smaller amounts of Horehound (*Marrubium vulgare*), grasses, and other annuals. Portions of this reach are constrained by shallow concrete banks and riprap. Overall habitat quality in this reach, with regard to potential for use by Southwestern Willow Flycatcher was judged to be moderate, based on vegetation structure, continuity with surrounding potential habitat, and disturbance levels.

The Devil canyon reach lies on either side of a concrete retention dam near the eastern boundary of the project site. Southern Cottonwood - Willow Riparian Forest is also present in this reach, but includes Goodding's Black Willow (*Salix gooddingii*), Fremont's Cottonwood (*Populus fremontii*), relatively more Giant Reed (*Arundo donax*), and less Coast Live Oak. Common understory plants included blackberry (*Rubus* sp.), sapling willows, phacelia (*Phacelia* sp.), Poison-oak (*Toxicodendron diversilobum*), California Mugwort (*Artemisia douglasiana*), and various annual grasses. Algae was very common in pools within the streambed. Overall habitat quality in this reach, with regard to potential for use by Southwestern Willow Flycatcher was judged to

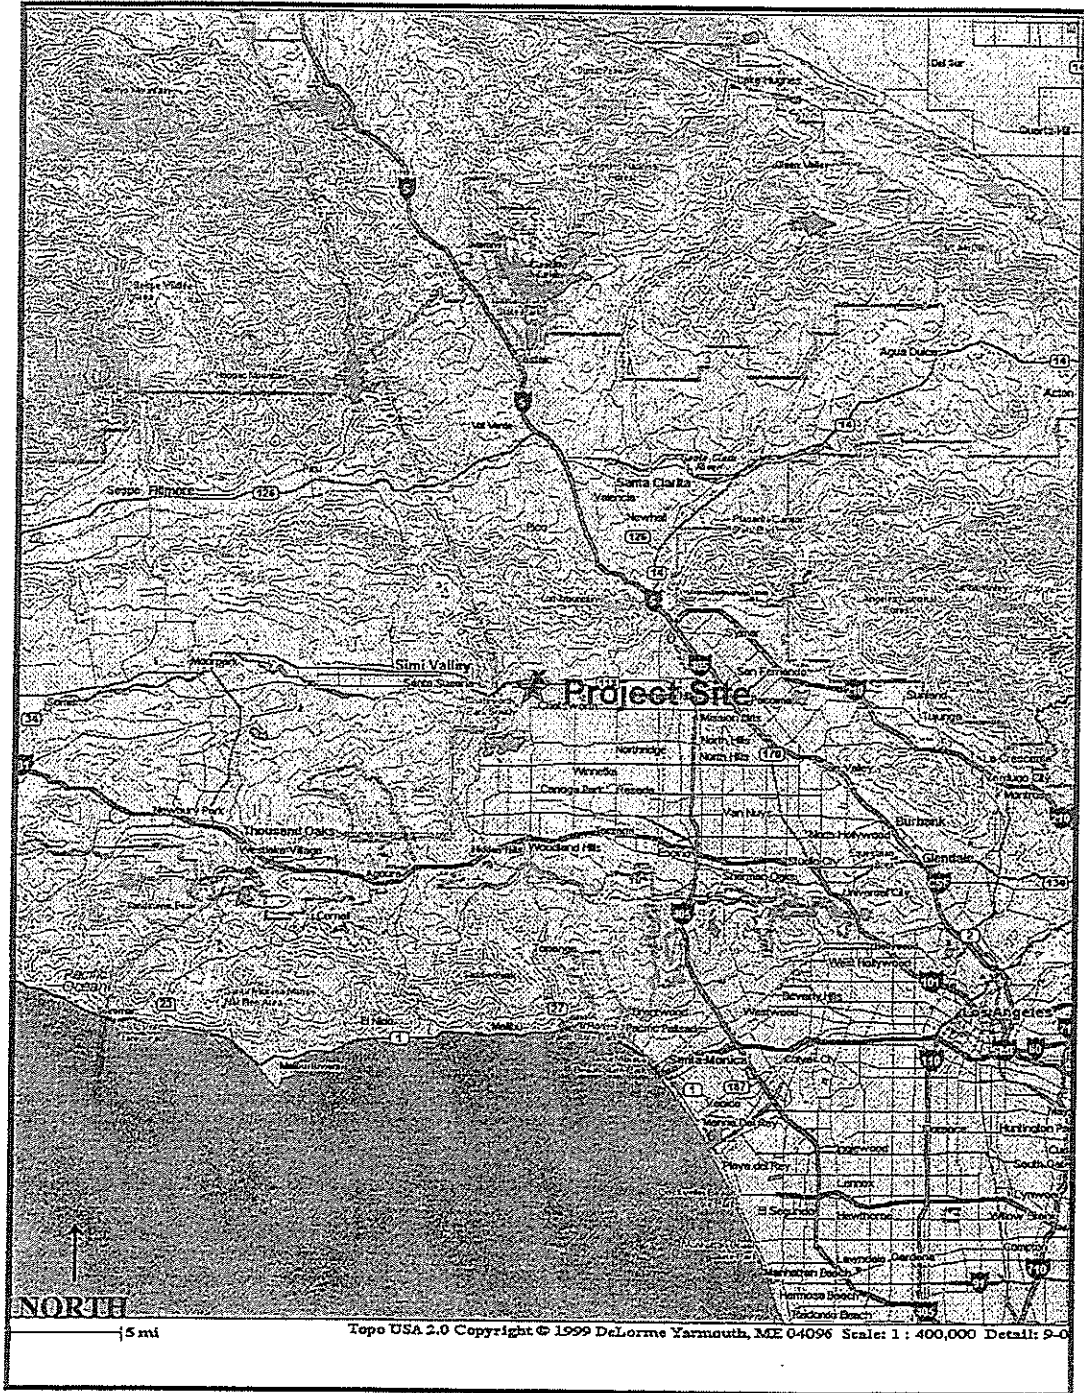

Figure 1

Project Site Vicinity
Chatsworth Ridge Estates Project, Los Angeles County, California

be moderate to low, based on vegetation structure (slightly more constrained in width and more open than in Browns Canyon), continuity with surrounding potential habitat, and disturbance levels.

On all three visits surface water was present in both drainages. Flow was variable during the survey period, with water present over as little as approximately 50-60 percent of Devil Canyon drainage length, but flowed throughout Browns Canyon drainage. The survey area is fairly lightly visited by people, with scattered hikers and vehicles along Brown's Canyon Road. None were seen along Devil Canyon drainage, though fairly fresh footprints from a single individual were seen on two of three visits.

During the survey, 73 species of vertebrate animals were detected in the survey area with totals of one amphibian, three reptile species, 14 mammal species, and 55 species of birds. The following species detected during the survey have special regulatory or management status: Cooper's Hawk (*Accipiter cooperii*; state Species of Special Concern), Western Yellow Warbler (*Dendroica petechia brewsteri*; state Species of Special Concern), and Ashy (=Southern California) Rufous-crowned Sparrow (*Aimophila ruficeps*; federal Species of Concern and state Species of Special Concern). A single pair of Coopers Hawks apparently nested in Devil Canyon (outcome unknown). A single Yellow Warbler noted on the first visit at the east end of the Devil Canyon reach was presumably a migrant as it was not noted again. Based on information from Browning (1994), this individual would most likely have been of the special status subspecies *Dendroica petechia brewsteri*. Rufous-crowned Sparrows were apparently present at low densities in the chaparral adjacent to the survey area throughout, visiting the riparian on a couple of occasions presumably for water.

Although no quantitative sampling was performed, bird species most commonly found during the survey visits were judged to be Anna's Hummingbird (*Calypte anna*), Bewick's Wren (*Thryomanes bewickii*), Wrentit (*Chamaea fasciata*), and House Finch (*Carpodacus mexicanus*).

3.0 FOCUSED SURVEY FOR SOUTHWESTERN WILLOW FLYCATCHER

The following subsections present background information, methods and results for this focused survey. This survey was conducted to determine the presence or absence of Southwestern Willow Flycatcher (*Empidonax traillii extimus*), following the current standard protocol (Sogge et al. 1997).

3.1 Background Information

The following information provides a relevant synopsis of the taxonomy, ecology and habitat requirements of Southwestern Willow Flycatcher, but is not intended to be exhaustive.

A small bird of muted colors, very similar in appearance to several other flycatchers, Willow Flycatcher (*Empidonax traillii*) is an insectivore, taking insects on the wing or gleaning them from foliage. The species as a whole was given protection by the state of California as an Endangered species on 03 December 1990, and the component subspecies breeding from southern California into western Texas, Southwestern Willow Flycatcher (*E.t. extimus*), additionally became a federally listed Endangered species as of 27 February, 1995 (USFWS 1995).

This subspecies (= "race") of the Willow Flycatcher was originally described about 50 years ago (Phillips 1948), but our current understanding of its identification and range is based upon detailed work by Unitt (1987), which indicates that it breeds from western Texas west through southern California, north to southern Utah and southern Nevada, and south into extreme northern Mexico. Within California, it breeds from the south fork of the Kern River near the southern end of the Sierra Nevada, thence coastward from at least Santa Barbara County

south to Baja California. The species as a whole is known to breed from near sea level to high mountain meadows, and this subspecies may be no exception in this regard. Winter range and habitats of Southwestern Willow Flycatcher are almost completely unknown, but the species as a whole is known to winter from southern Mexico south at least to Panama (AOU 1998).

Southwestern Willow Flycatchers are normally present in southern California on breeding grounds beginning in early May and continuing through at least late July, though timing of local birds is obscured by more abundant migrants of other subspecies passing through the area. Migrants of subspecies other than *E.t. extimus* are very widespread, and uncommon to fairly common as they pass through southern California, mainly from late May through mid-June, and again from late July through September. The period in which migrants of other subspecies are absent from southern California is approximately 14 June through 17 July (Unitt 1987).

As noted in the Federal Register final rule listing the species as endangered (USFWS 1995), the Southwestern Willow Flycatcher, "occurs in riparian habitats along rivers, streams, or other wetlands, where dense growths of willows (*Salix* spp.), *Baccharis* spp., Arrowweed (*Pluchea* spp.), buttonbush (*Cephalanthus* spp.), tamarisk (*Tamarix* spp.) Russian olive (*Eleagnus* spp.) or other plants are present, often with a scattered overstory of cottonwood (*Populus* spp.) . . . Throughout the range of *E.t. extimus*, these riparian habitats tend to be rare, widely separated, small and/or linear locales, separated by vast expanses of arid lands. The Southwestern Willow Flycatcher has experienced extensive loss and modification of this habitat and is also endangered by other factors including brood parasitism by the Brown-headed Cowbird."

3•2 Methods

From 29 May 1999 through 09 July 1999, Campbell BioConsulting conducted a focused survey for Southwestern Willow Flycatcher throughout all potentially suitable habitat within the survey area (Exhibit 1).

Surveys were conducted according to the current protocol for such work (see below). Component floral species, their physical structure, and condition were evaluated based on both personal experience with, and published literature on this subspecies' habitat requirements. See the discussion below for survey methods. Habitat structure was not analyzed quantitatively, and no attempt was made to define home ranges or territories. All habitats extending at least 30 meters (100 feet) beyond the survey area boundaries was also examined to provide context. All surveys were conducted by Kurt F. Campbell (permit # PRT-781485; exp. 18 Mar 2002). See Table 1 for dates, times and site conditions.

Table 1. Focused Survey Site Visits and Weather Conditions

Date	Times	Conditions
29 May 00	0530-0930	57°F (start); cloud cover 0%; wind calm; no dew; visibility good
11 June 00	0525-0900	53→73°F; cloud cover 0%; wind calm; no dew; visibility good
09 July 00	0525-0900	52→66°F; cloud cover 0→10%; wind calm; no dew; visibility good

The published survey methodology (Sogge et al. 1997) in effect at the time of the survey was followed. On all survey visits, all potential habitat was carefully checked for this species, including slow walking with frequent stops to listen and play taped Willow Flycatcher vocalizations. Tapes were played approximately every two minutes, or at distance intervals of approximately 75-100 feet (23-30 meters). At some points the habitat could be surveyed by walking along the road, while at other times it was necessary to walk at the riparian edge or to

carefully enter the riparian habitat in search of birds and vocalizations. The survey protocol to determine presence or absence of Southwestern Willow Flycatcher requires a federal 10(A)1(a) permit.

This USFWS-adopted protocol includes the following four basic elements: (1) preparation: the surveyor must be familiar with the species' habitats, behavior, and identification; (2) timing: three visits must be made to all potentially occupied habitat, each in a separate window (15 - 31 May; 01 -21 June; 22 June - 10 July), and with each visit no closer together than at 5-day intervals; (3) methods: at each site surveyors should cautiously and conservatively broadcast recorded vocalizations of Willow Flycatchers; (4) surveys should be limited to the morning period between one hour before sunrise and 1000. Additional details on methods are provided in Sogge et al. (1997). All protocol methods were followed for this survey.

The protocol for use within the entire range of the Southwestern Willow Flycatcher, including California, was modified shortly after the end of the current survey season (USFWS 2000), however changes in required procedure are stated to be applicable only to subsequent surveys.

3•3 Results

No Willow Flycatchers (of any subspecies) were detected in the survey area, and thus Southwestern Willow Flycatchers can be considered absent at this time. The nearest known breeding site in recent decades is from the Santa Clara River, roughly 12 to 15 miles north or northwest of the project site.

Part of the current protocol requirement for this species is to report on numbers and locations of all Brown-headed Cowbirds detected. Brown-headed Cowbirds (*Molothrus ater*) were detected on all three survey visits, as follows: 20 May, 3 males in Brown's Canyon and 1 male and 1 female in Devil Canyon; 11 June, none in Brown's Canyon and 5 males and 1 female in Devil Canyon; 9 July, none in Browns Canyon and 2 males in Devil Canyon. Because Brown-headed Cowbirds are not strongly territorial and home ranges are poorly defined, overlapping, and variable by time of day, often with separate foraging and egg-laying areas (Lowther 1993) exact locations of birds were not mapped in the field. In addition, anecdotal data such as that for cowbirds during a survey such as this are often poorly correlated to actual numbers of individual birds present (Verner 1985).

4•0 CONCLUSIONS

A focused survey was conducted for Southwestern Willow Flycatcher in approximately 8.1 acres (about 3.3 hectares) of potentially suitable habitat on the Chatsworth Ridge Estates project site, overlapping the northwestern edge of the City of Los Angeles, Los Angeles County. Habitat quality with regard to potential for use by Southwestern Willow Flycatcher was judged to be moderate to low, based on defined habitat characteristics and surveyor experience. Southwestern Willow Flycatcher is a state and federally listed Endangered species breeding across the southwestern United States from southern California to western Texas. Surveys were conducted in accordance with the applicable presence/absence survey protocol. Southwestern Willow Flycatcher was confirmed to be absent at this time. Should project actions affecting remaining potentially suitable habitat be delayed for more than one year after this survey was conducted (i.e., after July 2001), we strongly recommend either conducting a new survey or holding an informal consultation with the U.S. Fish and Wildlife Service and California Department of Game to confirm any assumption of the continued absence of the species along the surveyed reaches of Browns Canyon and Devil Canyon.

Please note that this report is not intended as a general analysis of biological issues on the site, and is not intended to provide interpretations of significance in light of the California Environmental Quality Act or any other environmental regulations at local, state or federal levels.

**APPENDIX A
PROJECT SITE PHOTOS**

1. The first part of the document discusses the importance of maintaining accurate records of all transactions and activities. This is essential for ensuring transparency and accountability in the organization's operations.

2. The second part of the document outlines the various methods and techniques used to collect and analyze data. This includes both qualitative and quantitative approaches, as well as the use of advanced statistical tools and software.

3. The third part of the document focuses on the interpretation and presentation of the results. This involves identifying key findings, trends, and patterns, and then communicating these insights in a clear and concise manner to the relevant stakeholders.

4. The final part of the document provides a summary of the overall findings and conclusions. This includes a discussion of the limitations of the study and suggestions for future research and improvements.

Photo 1. Devil Canyon at Saugus Road bridge, looking northwest. Note nonnative pines.

Photo 2. Devil Canyon, just northeast of Saugus Road bridge, looking east. This is the broadest area of riparian vegetation in the surveyed portion of this drainage.

Photo 3. Browns Canyon where creek crosses Browns Canyon Road, looking northwest. This is the approximate starting point for coverage of this reach.

Photo 4. Devil Canyon, looking east from Saugus Road bridge, viewing the same riparian area as in the previous photo. Note Giant Reed (*Arundo donax*) in foreground.

Photo 5. Browns Canyon, fairly typical view of understory, looking northeast.

Photo 6. Browns Canyon, looking approximately south. Note Coast Live Oaks on left (where creek is flowing) and willows on right.

Photo 7. Browns Canyon, looking south. Note broken concrete and debris (e.g., refrigerator in upper left), which was moderate to light in volume over most of the survey area.

595 Market Street, Suite 2400
San Francisco, California 94105

SUBJECT: Results of Biological Reconnaissance on 13-Acre Property Adjacent to the Chatsworth Ridge Estates Project Site, Los Angeles County, California.

Dear Mr. Garlinghouse:

Biologists from Glenn Lukos Associates, Inc. (GLA) examined the above-mentioned site on November 6, 2000 to evaluate potential biological and jurisdictional constraints associated with the property. The proposed project site is located in an unincorporated section of Los Angeles County near the City of Chatsworth [Exhibit 1]. The 13-acre site is depicted on the U.S. Geological Survey (USGS) 7.5 minute topographic map Oat Mountain, California (dated 1952 and photo revised in 1969) [Exhibit 2]. The topography of the site includes a manufactured slope adjacent to the terminus of Topanga Canyon Boulevard, a small gully, and a rocky peak sloping to and including Devil Canyon, a semi-perennial stream. The elevation of the site ranges from approximately 1,270 feet above mean sea level (MSL) in the southeastern section to approximately 1,600 feet above MSL in the middle of the property. Soils on the site consist of sandy loams weathered from sandstone bedrock, along with alluvial soils in drainages.

METHODOLOGY

Sensitive biological resources present, or potentially present were identified through a literature review using the California Natural Diversity Data Base (CNDDDB) (2000). The brief field examination was focused on a number of objectives: (1) vegetation mapping; (2) a general floristic plant survey; (3) a general wildlife survey; and (4) a focused survey for Santa Susana tarplant. Because of the timing of GLA's examination of the property, the results provided in this letter report are preliminary and must be verified by in-season surveys for many of the sensitive species mentioned below.

Vegetation associations were mapped in the field directly onto acetate overlays of an 80-scale black-and-white aerial photograph of the site. Vegetation associations were mapped based upon descriptions provided by Holland (1986) with, as appropriate, modifications to more accurately

characterize site conditions.

All plant species encountered during the field surveys were identified and recorded following the guidelines adopted by CNPS and CDFG, as described by Nelson (1994). Scientific nomenclature and common names used in this report follow Hickman (1993). When not available in Hickman, common names are taken from McAuley (1985), Roberts (1998), or Beauchamp (1986). As mentioned previously, the November survey would not have resulted in the detection of many annual species, or other species not in bloom at the time of the survey. Santa Susana tarplant (*Hemizonia minthornii*), a state-listed species, is known from the area and was the only target special-status plant capable of being detected in November. GLA therefore did conduct a focused survey for Santa Susana tarplant.

Wildlife species as detected during field surveys by sight, calls, tracks, scat, or other sign were recorded. No focused surveys for special-status wildlife were attempted, because November is outside the time frame required by protocols for virtually all target species potentially occurring on the site.

RESULTS

Vegetation

The site is dominated by three vegetation communities: chamise chaparral (10.62 acres), willow woodland (1.79 acres), and oak woodland/willow woodland ecotone (0.58 acre). The chaparral is dominated by chamise (*Adenostoma fasciculatum*), black sage (*Salvia mellifera*), laurel sumac (*Malosma laurina*), our Lord's candle (*Yucca whipplei*), California buckwheat (*Eriogonum fasciculatum*) hoaryleaf ceanothus (*Ceanothus crassifolius*) and deerweed (*Lotus scoparius*). The willow woodland is dominated by arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), mule fat (*Baccharis salicifolia*), and western sycamore (*Platanus racemosa*). The understory includes California blackberry (*Rubus ursinus*), poison oak (*Toxicodendron diversilobum*), and mugwort (*Artemisia douglasiana*). The oak/willow woodland ecotone includes a number of coast live oak (*Quercus agrifolia*) trees. Willow woodland (i.e., Southern Mixed Riparian Forest) is ranked as S2.1 ("very threatened"), with a small number of occurrences, individuals, or acres) by CDFG. All plant species recorded for the property are provided in Appendix A.

Santa Susana Tarplant

The CNDDDB revealed several occurrences of Santa Susana Tarplant in the vicinity of the site and the Santa Susana Pass. Specifically, Occurrence Number 11 of the CNDDDB is apparently very close to the site. The CNDDDB states that Occurrence Number 11 is "near the north terminus of Topanga Canyon Boulevard, and the Simi Valley Freeway."

A cut slope at the end of Topanga Boulevard does support Santa Susana tarplant, but the three individuals noted were located west of the property on another parcel. Two of the three plants were still in bloom on November 6. While the portion of the cut slope on the property appears to be similar to the area west of the property, no Santa Susana tarplant was detected. The bottom third of the slope has been "weed-whipped", apparently for fuel modification. If this activity has been ongoing, it would likely have resulted in the extirpation of Santa Susana tarplant from the site. The three individuals found off site were above the zone of maintenance and appeared healthy. A second potential impact to tarplant in the vicinity is the prevalence of the non-native fountain grass (*Pennisetum setaceum*) that dominates the cut slope. This aggressive weed would likely prevent Santa Susana tarplant from becoming established on the slope. While there are some boulders and other rock outcrops on the remainder of the site representing potential habitat, no Santa Susana tarplant was detected.

Plummer's Mariposa Lily

Plummer's mariposa lily (*Calochortus plummerae*) is known from the adjacent property. Suitable soils, slope, aspect, and vegetative cover are present on the site. Approximately 30-40 dead fruiting stalks were identified as genus *Calochortus*, potentially *C. plummerae*, but a positive identification and assessment of numbers cannot be performed without flowering-season surveys.

Wildlife

The brief examination of the site revealed a limited number of wildlife species. Two special-status species were identified: Cooper's hawk (*Accipiter cooperii*) and ashy rufous-crowned sparrow (*Aimophila ruficeps canescens*). The Cooper's hawk is a CDFG Species of Special Concern. Cooper's hawks are found in woodland habitats. They prey primarily on birds but they are known to eat small mammals, reptiles, amphibians, insects and fish. The ashy rufous-crowned sparrow, also a CDFG Species of Special Concern, is a resident species frequently found in coastal sage scrub and in other xeric habitats. Like other sparrows, it primarily eats seeds and insects. A list of all the wildlife species detected on the site is provided in Appendix A.

Jurisdictional Areas

A small gully is located in the southern end of the property. This feature does not exhibit an ordinary high water mark (OHWM) and is therefore not subject to Corps/CDFG jurisdiction. A drainage on the west side of the property and Devil Canyon and associated riparian vegetation are subject to Corps and CDFG jurisdiction.

POTENTIAL CONSTRAINTS/SURVEY NEEDS

The 13-acre site may be added to the Chatsworth Ridge Estates development project. Pursuant to the California Environmental Quality Act (CEQA), existing biological resources would need to be documented. Likewise, an impact analysis would need to be performed for the portion of the 13-acre parcel proposed for development.

The following tasks may need to be completed for the project Final Environmental Impact Report (FEIR); boldface indicates tasks that would likely be required:

- A. **Floristic plant surveys and focused special-status plant surveys**
 - 1. **Braunton's Milkvetch (*Astragalus brauntonii*)**
 - 2. **Nevin's Barberry (*Berberis nevinii*)**
 - 3. **Catalina Mariposa Lily (*Calochortus catalinae*)**
 - 4. **Slender Mariposa Lily (*Calochortus clavatus* var. *gracilis*)**
 - 5. **Plummer's Mariposa Lily-*Calochortus plummerae***
 - 6. **San Fernando Valley Spineflower (*Chorizanthe parryi* var. *fernandina*)**
 - 7. **Slender-Horned Spineflower (*Dodecahema leptoceras*)**
 - 8. **Robinson's Pepper grass (*Lepidium virginicum* var. *robinsonii*)**
 - 9. **Ocellated Humboldt Lily (*Lilium humboldtii* ssp. *ocellatum*)**
 - 10. **Fish's Milkwort (*Polygala cornuta* var. *fishiae*)**
- B. **General wildlife surveys**
- C. **Analysis of impacts to vegetation, wildlife, and special-status plants (if present)**
- D. **Jurisdictional delineation for Devil Canyon and tributary drainage upstream from the debris dam (optional - would increase acreage of preserved jurisdictional areas for CEQA and agency permitting)**

- E. Focused surveys for red-legged frog, least Bell's vireo, southwestern willow flycatcher (It is unknown if these surveys would actually be required by the agencies, so far we have had no listed species elsewhere in Devil Canyon. Since the portion of Devil Canyon associated with the 13-acre parcel is to be preserved, this task is likely optional.)
- F. Oak Tree survey

Task A and subtasks 1-10 above would have to be performed during the spring and early summer. Task B is usually performed during the spring and summer, but could probably be performed now. Task C would occur after tasks A and B were completed to the lead agency's satisfaction. Tasks D and F could be performed at any time and Task E must be performed in the spring/summer.

POTENTIAL IMPACTS

The latest version of the grading plans¹ depicts approximately 4.13 acres of impact to the 13-acre site. The impacted area is dominated by chamise chaparral. No other vegetation communities would be impacted by the proposed development.

Focused surveys will be conducted to determine whether the 13-acre site currently supports sensitive species. If sensitive species are identified on the property, the level of impacts will be determined at that time. If proposed development within the 13-acre site will impact sensitive resources, these impacts would be mitigated below a level of significance.

Corps/CDFG Jurisdiction.

The proposed development does not appear to impact jurisdictional areas.

Special-Status Plants

Of the plants species identified above, only Plummer's mariposa lily is likely to be identified within the proposed development area. If Plummer's mariposa lily is impacted by the proposed development, mitigation will consist of 1:1 replacement of individuals. A qualified restoration biologist/botanist (Project Monitor) will oversee all aspects of the Plummer's mariposa mitigation plan. The Project Monitor will mark individual plants during the spring or early summer with pin

¹ A new set of plans dated May 4, 2000 depicting the proposed development on the 13-acre parcel were transmitted to GLA on November 3, 2000.

flags to aid in the location of plants after fruits have matured. Seed and/or bulbs will be collected from onsite populations during the summer or fall, prior to site grading. Seed will be collected in late July or August, depending on the level of maturity of the seeds. Collected seeds will be stored for later propagation. In addition, bulbs of dormant plants will be dug up from areas with particularly dense populations of Plummer's mariposa during August or September and stored for later transplanting.

Propagated mariposa lilies typically germinate at approximately 80%. Therefore, at least 2,200 seeds and/or bulbs will be planted in a nursery to ensure that at least 1,700 plants are produced. Seed-propagated plants will be grown in the nursery for two years to allow the bulbs to reach optimal transplanting size. Bulbs collected from the field will be transplanted the fall/winter after collection to suitable locations within open space areas on the project site. In addition, any remaining seed will be hand broadcast into mitigation areas during the first or second fall/winter after collection.

The propagated plants, directly relocated bulbs, and remaining seed will be dispersed into appropriate habitats as directed by a restoration biologist. These areas will be chosen within or adjacent to existing Plummer's mariposa lily populations, and may include areas disturbed by grading of the project. All seeds and bulbs will be transplanted by the end of the second year after collection. A two-year monitoring program will be conducted to evaluate the mitigation sites and ensure that the 1:1 ratio has been achieved.

Special-Status Wildlife

Two special-status species have been identified from the 13-acre property: Cooper's hawk and ashy rufous-crowned sparrow. To mitigate for potential losses to these species, active nests will be avoided. Prior to any construction activity, the project applicant shall have a qualified biologist survey the project site for the presence of any occupied raptor nests. If such a nest is found, it shall be protected until nesting activity has ended to ensure compliance with Section 3503.5 of the California Fish and Game Code. Measures to ensure protection of the nesting raptor will be determined by the monitoring biologist and will depend on factors such as the species of raptor nesting and the construction schedule.

In addition, if grading or clearing of vegetation is scheduled to take place during the nesting season for migratory birds (March 15-August 15), a qualified biologist will survey areas to be graded no more than three days prior to the start of work. If active nests of migratory birds are located, measures to ensure protection of the nesting migratory bird will be determined by the monitoring biologist and will depend on factors such as the bird species and the construction schedule. Construction buffer zones for active raptor nests, if required, shall be a minimum of

500 feet and 200 feet for passerines.

Through the implementation of these mitigation measures, development of the 13-acre parcel would not result in significant impacts to biological resources.

Should you have any questions regarding the methodology or findings of this report, please call me at (949) 837-0404.

Sincerely,

APPENDIX A
FAUNAL AND FLORAL COMPENDIA
INTRODUCTION TO FLORAL AND FAUNAL SURVEY

Floral taxonomy used in this report follows the Jepson Manual (Hickman 1993) and, for sensitive species, the California Native Plant Society's Rare Plant Inventory (5th Edition) (Skinner and Pavlik 1994). Additional common plant names are taken from Munz (1974), Beauchamp (1986), and Roberts (1998). Vertebrates identified in the field by sight, calls, tracks, scat, or other signs are cited according to the nomenclature of Collins (1997) for amphibians and reptiles, AOU (1998) for birds, and Jones et al. (1992) for mammals.

APPENDIX C

NATIONWIDE PERMIT AUTHORIZATION

DEPARTMENT OF THE ARMY
LOS ANGELES DISTRICT, CORPS OF ENGINEERS
P.O BOX 532711
LOS ANGELES, CALIFORNIA 90053-2325

March 27, 2000

REPLY TO
ATTENTION OF.

Office of the Chief
Regulatory Branch

Presidio Chatsworth Partners, LLC.
c/o Glenn Lukos Associates
23441 South Pointe Drive, Suite 150
Laguna Hills, California 92653

Dear Mr. Lukos:

This is in reply to your application (File No. 2000-00951-AOA) dated February 11, 2000, for a Department of the Army Permit to impact 0.41 acres of waters of the United States for the construction of storm drains, debris basins and the placement of compacted earthen material associated with a 500-unit residential development (Chatsworth Ridge Estates) in unnamed tributaries to Devil and Brown Canyon near the City of Chatsworth, Los Angeles County, California.

The Corps of Engineers has determined that your proposed activity, along with the attached special conditions, complies with the terms of nationwide permit NW26 [Federal Register, Dec.13, 1996, pp.65874-65922] for discharges of dredged or fill material into headwaters and isolated waters provided that the activity meets all of the following criteria in the permit terms and conditions (Enclosure). For the purposes of this NWP, the acreage of loss of waters of the United States includes the filled area plus waters of the United States that are adversely affected by flooding, excavation or drainage as a result of the project. The 3 acre and 1/3 acre limits of NW 26 are absolute, and cannot be increased by any mitigation plan offered by the applicant or required by the District Engineer. Whenever any other NWP is used in conjunction with this NWP, the total acreage of impacts to waters of the United States of all NWPs combined, can not exceed 3 acres.

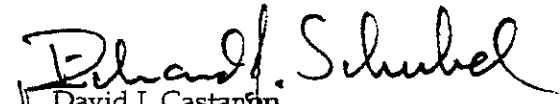

However, at this time we do not have sufficient information to determine whether your proposed activity complies with the nationwide permit General Conditions described in Part 330, Appendix A(C)

Until you receive written notification from the Corps that the outstanding General Condition listed above has been met, you are not authorized to begin your proposed activity. This letter of provisional verification is valid for a period not to exceed two years unless the nationwide permit is modified, reissued, revoked, or expires before that time. Presently, all nationwide permits are scheduled to expire on February 11, 2002 except nationwide permit 26 which is currently scheduled to expire on June 7, 2000. However, the Corps has extended the expiration date for projects previously approved under nationwide permit number 26 to February 11, 2002 (See March 9, 2000, Federal Register, 65 FR 12818). As a result, this letter of verification is valid until February 11, 2002. It is incumbent upon you to remain informed of

changes to the nationwide permits. We will issue a public notice announcing the changes when they occur.

If you have any questions, please contact Aaron Allen of my staff at (213) 452-3413.

Sincerely,

for David J. Castanon
Chief, North Coast Section
Regulatory Branch

I. INTRODUCTION

Overview

The Deerlake Ranch Mitigation Plan provides a comprehensive program of project-initiated measures that avoid, minimize, and compensate for impacts to the Plummer's Mariposa Lily, oak and riparian woodland, and other sensitive plants and wildlife. The primary objective of the mitigation described herein is to decrease impacts of project development on sensitive biological resources to less than significant, as defined by the California Environmental Quality Act (CEQA). With review and acceptance of the plan by the County of Los Angeles, the mitigation measures herein are incorporated by reference into the Draft Environmental Impact Report (EIR). Upon receiving public comments to the Draft EIR, if required, revisions would be published in the Final EIR. Further, this plan provides mitigation suitable for integration in the project's California Department of Fish and Game (CDFG) Section 1603 Agreement, Army Corps Nationwide Permit, and California Section 401 Water Quality Certification.

Mitigation Goals for Biological Resources

Mitigation goals for the proposed project are based on a tiered approach of avoidance, minimization, and compensation. The current and proposed achievement of each goal is highlighted¹ below.

Avoidance - Project redesign facilitated avoidance of the majority of onsite wetlands, riparian and oak woodland, and other sensitive habitats. Through the preservation of these onsite drainages, additional resources were also avoided including wildlife linkages, sensitive wildlife, and potential nesting sites of sensitive birds, such as the Cooper's Hawk. In addition, upland areas of the site containing numerous Plummer's mariposa lilies are proposed as open space to preserve natural resources as well as this sensitive plant. Much of the avoided sensitive habitats would be dedicated to the Santa Monica Mountains Conservancy.

Minimization - Impacts on wetlands and riparian woodland are also minimized through the inclusion of buffer zones from the boundary of the stream-side tree canopy (which also excludes most of the area from fuel-modification impacts). Other minimization efforts include limited use of night lighting, use of native vegetation in landscaping, and purchase of additional property to provide a second access rather than crossing sensitive habitats.

Compensation - To compensate for unavoidable impacts to sensitive biological resources, the applicant proposes to purchase offsite property(s), as approved by the County of Los Angeles and CDFG for natural habitat preservation. The site(s) would function as a nature preserves, be dedicated to a government agency or conservation organization, or be placed under a conservation easement and retained by the applicant. The criteria for an offsite mitigation site(s) includes the presence of occupied and potential Plummer's mariposa lily habitat, and the existence of other sensitive habitats as described in the following sections. Further, the property(s) must support foraging and/or breeding habitat for the sensitive wildlife species observed on the project site.

In addition to the above, the project would initiate a program of Plummer's mariposa lily seed and bulb salvage, propagation, and transplanting. The purpose of this program is to retrieve a sizable portion of the onsite bulbs for use in both onsite and offsite habitat enhancement. Another component of this effort is researching and documenting methods that lead to successful long-term establishment of transplanted bulbs. This includes seeds and bulbs collected and transplanted directly to a site within the same year, stored bulbs, and bulbs grown from site-collected seed in a nursery.

¹ For additional details on avoidance and minimization, please refer to the project Draft EIR.

The salvage program will consist of the following components:

- A. Prior to grading, collect seed from a random selection of all visible and accessible plants, salvage all flagged/mapped bulbs and any uncovered during removal. Collect a minimum of 4,000 (this represents a little over a 2:1 replacement ratio of the single greatest population count conducted onsite to date). If 4,000 bulbs do not inhabit the project site, collect all bulbs found.
- B. Store all seeds and bulbs at a qualified native plant nursery.
- C. Use 40% of the bulbs for transplantation to onsite and offsite preserved habitat in the fall/winter immediately following salvage.
- D. Propagate 20% of the bulbs and all seed at a qualified native plant nursery to collect seed for starting new plants that will be transplanted to preserved areas both onsite and offsite.
- E. Store for a period of 5 years 40% of the bulbs for annual or bi-annual planting in preserved areas, as determined by a qualified biologist.
- F. Maintain all transplanted bulbs, including weed control.
- G. Conduct monitoring and reporting.

Plummer's mariposa lily- Calculation of Acreage of Habitat and Population Size

Onsite surveys of the Plummer's mariposa lily population and habitat have been conducted over the last three years including Summer 2001. Preliminary results indicate that the above ground lily population ranges from approximately 400 individuals (Envicom Corporation 2001) to approximately 1,800 individuals (Glen Lukos & Associates 1999/2000). The number of individual plants not blooming in any particular season likely accounts for this difference in population size from year to year. Because of this variation from year to year in above appearance of ground stalks and flowers, a map is currently being prepared that integrates the previous years' findings with this year's survey. To produce the map, each accessible plant or cluster, are being located in the field using engineering survey techniques. In this manner, the locations are linked to the site-specific topography, thus the bulbs can then be relocated, and salvaged, even if no above ground stalk is visible. In addition, site surveys estimate the acreage of Plummer's mariposa lily habitat (potential and occupied) to be 61.04 acres. With this acreage calculation there will be a direct nexus between impacts to habitat and the acreage of mitigation land that would assist in reducing project impacts to this sensitive plant to less than significant.

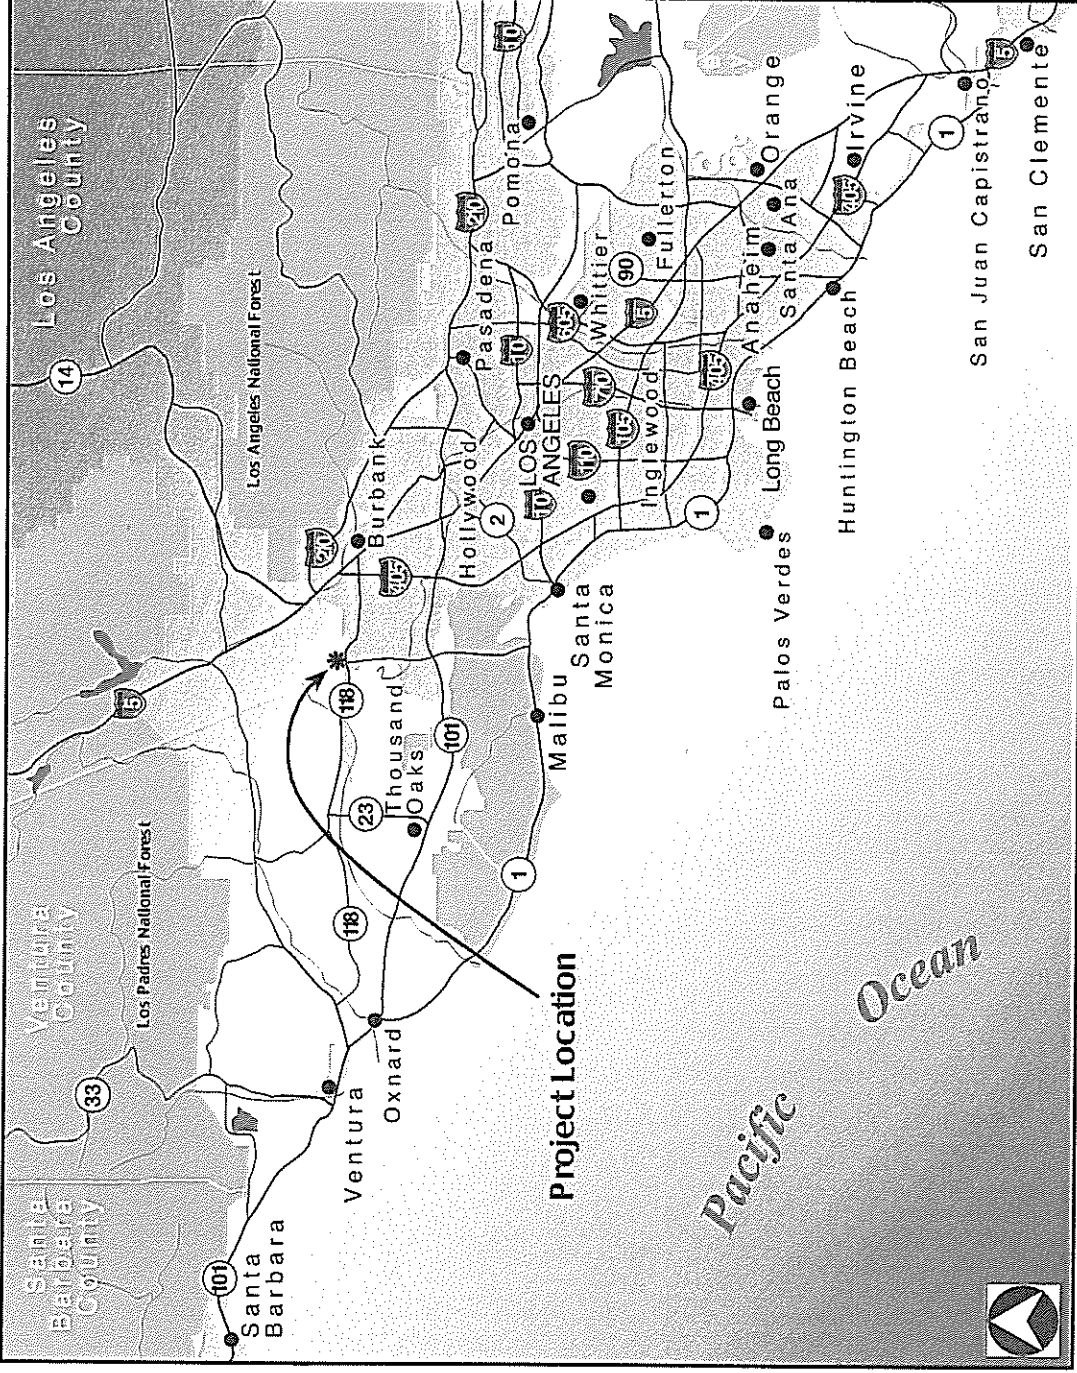

Project Description

Location/Site Conditions

Deerlake Ranch is located within the northwestern San Fernando Valley area of Los Angeles County, specifically in the south-facing foothills of the Santa Susana Mountains (Figure 1). The project comprises approximately 230 acres of undeveloped land (Figure 2). This site is located on a mesa, the Deerlake Highlands, and has an average elevation of approximately 1,325 feet above sea level. This plateau is generally flat with rolling hills and is bordered on the north by steep and rugged hills that trend westward. Devil Canyon borders the plateau to the south and west, which bisects the project site. Browns Canyon borders the plateau to the east. Soils on the site consist of sandy soils weathered from sandstone bedrock, along with alluvial soils in drainages. Portions of the property were previously developed and/or graded for homes, roads, and equestrian trails.

Project Characteristics

The project would consist of 485 single-family homes on a total of 230 acres (Figure 3). The project proposes to impact a total of 176.44 acres of vegetation for project construction. This consists of 153.90 acres of permanent impact and 22.54 acres of partial impact from fuel modification, as required by the County. The impacts on natural habitat include mass grading, remedial grading, road construction, fuel modification, and utility easements.

II. SUMMARY OF BIOLOGICAL RESOURCES

Introduction

The 230.58 acre site consists of native and non-native vegetation that supports a variety of native wildlife species within diverse habitats and vegetation communities. In addition, the Deerlake Ranch site provides niches for wildlife including nesting, foraging, resting, and cover. The removal of native vegetation will change the functions and values of the site and the surrounding open space. Wildlife composition on the newly built site will change to animals associated with human habitation such as the house finch, raccoon, house mouse, and others. Therefore, by understanding the existing resources, it is possible to "replace" a few of the less complex values, such as food sources. While, however, the landscaped slopes of the future Deerlake Ranch will not resemble the existing natural condition, the newly established plant communities can provide, to a minor degree habitat for animals. This summary of biological resources provides the reader with the background needed to understand the conditions of the project site.

Glen Lukos Associates conducted biological field surveys on the approximate 230-acre site during March to August 1998, June 1999, April through July 2000, and November through December 2000. The following information was acquired from the *Biological Technical Report - Deerlake Ranch Development Project - Los Angeles County, California* prepared by Glen Lukos Associates December 28, 2000. Please refer to this document for a more detailed account of the fieldwork and literature review.

Plant communities

Vegetation consists of chaparral, coastal sage scrub, coast live oak woodland, non-native grassland over the upland areas, and in Devil Canyon a well-developed willow riparian forest that traverses from northwest to southeast across the property. This willow riparian forest converges with Brown's Canyon just offsite, to the east. There are numerous sandstone rock outcrops scattered over the landscape. Non-native vegetation includes annual grasses and eucalyptus groves.

Chaparral

The predominant species of the chaparral are chamise (*Adenostoma fasciculatum*), mountain mahogany (*Cercocarpus betuloides*), laurel-leaf sumac (*Malosma laurina*) and black sage (*Salvia mellifera*). Chamise chaparral occupies flat areas and slopes throughout most of the site and is the predominant vegetation association. A total of approximately 190.73 acres of chamise chaparral has been identified on the project site. Other shrubs include Mexican elderberry (*Sambucus mexicana*), Our Lord's candle (*Yucca whipplei*), California buckwheat (*Eriogonum fasciculatum*) and deerweed (*Lotus scoparius*). The understory is composed of annuals including non-native tocolote (*Centaurea melitensis*), common cryptantha (*Cryptantha intermedia*), various suncups (*Camissonia* ssp.), common catchfly (*Silene gallica*), and various non-native grasses.

Coastal sage scrub

The total area of coastal sage scrub identified on the project site is approximately 2.39 acres and is dominated by California sagebrush (*Artemisia californica*), deerweed (*Lotus scoparius*), and California buckwheat (*Eriogonum fasciculatum*). The understory is composed of slender wild oats (*Avena barbata*), tocolote, and other mostly non-native herbaceous species. The coastal sage scrub occurs in a previously graded homestead near the middle of the site.

Non-native Grassland/Previously Disturbed

The project site includes approximately 7.56 acres of non-native grassland. Non-native grassland and disturbed soils consist of ripgut brome (*Bromus diandrus*), slender wild oats (*Avena barbata*), black mustard (*Brassica nigra*), summer mustard (*Hirschfeldia incana*), common catchfly (*Silene gallica*), and tocolote. Scattered non-native eucalyptus trees are found in flat areas throughout the site and

seedlings have begun to colonize riparian areas. The project site consists of approximately 0.18 acres of eucalyptus grove.

Previously developed areas that have been graded or repeatedly cleared of vegetation on the project site total approximately 13.53 acres. Some areas exhibit bare earth and rocks, while other areas are dominated by plant species such as summer mustard, slender wild oats, storksbill (*Erodium* spp.), and cheeseweed (*Malva parviflora*).

Coast Live Oak Woodland

The total area of oak woodland on the project site is approximately 5.73 acres with the dominant overstory species being coast live oak (*Quercus agrifolia*). However, individual oak trees are found in other vegetation associations on the site. The understory includes shrubs such as toyon (*Heteromeles arbutifolia*), Southern California black walnut (*Juglans californica*), Mexican elderberry, poison oak (*Toxicodendron diversilobum*), and non-native grasses. Coast live oak woodland on site was most often observed adjacent to drainages, or on shaded, north facing slopes.

Willow Woodland

The total area of willow woodland on the project site is approximately 9.88 acres. Dominant vegetation within this association includes arroyo willow (*Salix lasiolepis*), red willow (*Salix laevigata*), mule flat (*Baccharis salicifolia*), and Fremont's cottonwood (*Populus fremontii*). Less common overstory species include black cottonwood (*Populus balsamifera* ssp. *trichocarpa*), western sycamore (*Platanus racemosa*), Southern California black walnut and occasional box elder (*Acer negundo* var. *californicum*). Willow woodland occurs in areas adjacent to the Devil Canyon drainage and smaller tributaries. The habitat has been invaded by non-native giant reed (*Arundo donax*) in parts of lower Devil Canyon.

Oak Woodland/Willow Woodland

This association is characterized by small stands dominated by coast live oak and willows (*Salix* spp.) found on terraces above Devil Canyon Creek, primarily upstream from the Devil Canyon debris dam. The total area on the project site is approximately 0.58 acres.

Wildlife

Wildlife use of the site is high due to the variety of vegetation types. Refer to the *Biological Technical Report* prepared by Glen Lukos Associates for a detailed account of species present and methodology used to determine their presence.

Amphibians

Willow and oak woodland habitats support the amphibian species identified on the project site. These areas provide potential habitat for amphibian species adapted to drier conditions. Amphibians often require a source of standing water, which is found on site intermittently, however some species can survive in drier climates in moist environments such as leaf litter, fallen logs, or burrowing in the soil. Only two amphibian species were observed on site: Pacific treefrog (*Pseudacris regilla*) and western toad (*Bufo boreas*). Additional amphibian species that could potentially occur onsite include the Pacific slender salamander (*Batrachoseps pacificus*), California newt (*Taricha torosa*), ensatina (*Ensatina eschscholtzii*), arboreal salamander (*Aneides lugubris*), and black-bellied salamander (*Batrachoseps nigriventris*).

Reptiles

Coastal sage scrub and chaparral communities identified onsite are utilized nearly year-round by a large number of reptile species. Species identified during site surveys include the western fence lizard (*Sceloporus occidentalis*), side-blotched lizard (*Uta stansburiana*), southern alligator lizard

(*Gerrhonotus multicarinatus*), western skink (*Eumeces skiltonianus*), California whipsnake (*Masticophis lateralis*), gopher snake (*Pituophis melanoleucus*), orange-throated whiptail (*Cnemidophorus hyperthrus*), and western rattlesnake (*Crotalus viridis*).

The reptile species identified within the grassland communities onsite are expected to vary over the course of the year depending on abundance of grasses and availability of cover. Species observed during site surveys include the western fence lizard, side-blotched lizard, and western rattlesnake.

Riparian communities tend to exhibit low reptile species diversity. However, reptiles were identified near the edge of the intermittent drainages. These included southern alligator lizard, California whipsnake, side-blotched lizard, and western fence lizard.

Birds

Birds were the most widely observed vertebrate on the project site. The scrub communities onsite are generally composed of low dense vegetation, which provides breeding habitat for resident bird species. Commonly observed species include the California towhee (*Pipilo crissalis*), wrentit (*Chamaea fasciata*), Bewick's wren (*Thryomanes bewickii*), Anna's hummingbird (*Calypte anna*), western scrub jay (*Aphelocoma coerulescens*), and California thrasher (*Toxostoma redivivum*). Migratory species that utilize coastal sage scrub at various times include the white-crowned sparrow (*Zonotrichia leucophrys*), song sparrow (*Melospiza melodia*), and golden-crowned sparrow (*Zonotrichia atricapilla*).

Onsite chaparral vegetation provides habitat for species such as the western scrub-jay, California thrasher, wrentit, Bewick's wren, California quail, California towhee, and Anna's hummingbird. Migratory species include the white-crowned sparrow, Costa's hummingbird (*Calypte costae*), and fox sparrow (*Passerella iliaca*).

Grassland communities provide habitat for resident and migratory species such as the house finch (*Carpodacus Mexicana*), horned lark (*Eremophila alpestris*) and lark sparrow (*Chondestes grammacus*).

Sensitive bird species identified onsite include Cooper's hawk (*Accipiter cooperii*), western yellow warbler (*Dendroica petechia brewsteri*), and ash rufous-crowned sparrow (*Aimophil ruficeps canescens*).

Mammals

The combination of chaparral, coastal sage scrub, grassland, and riparian communities provides habitat for numerous mammal species. Species identified include Audubon's cottontail (*Sylvilagus audubonii*), California ground squirrel (*Spermophilus beecheyi*), deer mouse (*Peromyscus maniculatus*), bobcat (*Lynx rufus*), gray fox (*Urocyon cinereoargenteus*), and California vole (*Microtus californicus*).

Sensitive Vegetation Communities

Coastal sage scrub is considered a sensitive vegetation type throughout much of Southern California primarily in regions known to support the federally-listed threatened coastal California gnatcatcher. Coastal sage scrub has an S3.1 (between 10,000 and 50,000 extant acres and high level of threat) ranking by the CDFG. Approximately 2.39 acres of coastal sage scrub habitat has been identified onsite. The onsite community of coastal sage scrub habitat has been highly disturbed from fire impacts and is in a degraded condition. The proposed project would remove the total 2.39 acres of coastal sage scrub existing onsite. Protocol surveys determined that no California gnatcatchers are located onsite.

Willow Woodland is ranked as S2.1 ("very threatened"), with a small number of occurrences, individuals, or acres) by CDFG. This site supports approximately 9.88 acres of willow woodland in Devil Canyon. The proposed project would remove 0.02 acre for grading and 0.01 acre for fuel modification. This type of habitat is known to support a wide diversity of wildlife.

Coast Live Oak Woodland is not listed by CDFG as a sensitive vegetation type. However, the County of Los Angeles has identified the habitat as sensitive. At least one area in the northern portion of the project site has burned recently and is dominated by young trees. In general, the larger trees are associated with canyons and north-facing slopes. The project site supports 5.73 acres of coast live oak woodland, of this amount, 1.30 acres would be impacted by the proposed project.

Sensitive Plant Species

Focused surveys were conducted for special-status plant species with the potential to occur on the project site. These surveys of the project site identified two special-status plant species inhabiting the area: Plummer's mariposa lily (*Calochortus plummerae*) and southern California black walnut (*Juglans californica*) and one County-considered sensitive plant, coast live oak.

Plummer's mariposa lily is a federal Species of Concern and a CNPS 1B species. A detailed description of the Plummer's mariposa lily, project impacts, and mitigation for the lily is presented in the following sections.

Southern California black walnut is listed as a CNPS List 4. Scattered individuals of this species have been identified on the site in Devil Canyon. The project would not remove any walnut trees.

Coast live oaks have been identified on the project site, which is subject to County of Los Angeles Oak Tree Ordinance (No. 93-0018). A total of 353 oak trees over eight inches in diameter at breast height were surveyed on the project site. The project proposes removal of 65 oak trees for construction purposes, of which none are heritage oaks. The County of Los Angeles designates coast live oaks as "sensitive."

Ten other special status species have the potential to occur in this habitat, however they were not identified during the surveys. These species include Brauton's milkvetch (*Astragalus brauntonii*), Nevin's barberry (*Berberis nevinii*), Catalina mariposa lily (*Calochortus catalinae*), Slender mariposa lily (*Calochortus clavatus*), San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*), Slender-horned spineflower (*DodecHEMA leptoceras*), Santa Susana tarplant (*Hemizonia minthornii*), Robinson's pepper grass (*Lepidium virginicum* var. *fishiae robinsonii*), Ocellated Humboldt lily (*Lilium humboldtii* ssp. *ocellatum*), and Fish's milkwort (*Polygala cornuta*).

Sensitive Wildlife

The project site does not support any federally or state listed endangered, threatened, or rare species.

History of Protocol Surveys

Wildlife species were detected and recorded during field surveys by sight, calls, tracks, scat, nests or other signs. Species with the potential to occur, but not observed during USFWS protocol surveys include California red-legged frog (*Rana aurora draytonii*), Two-Striped Garter snake (*Thamnophis hammondi*), San Diego horned lizard (*Phrynosoma coronatum blainvillei*), Southwestern willow flycatcher (*Empidonax traillii extimus*), Coastal California gnatcatcher (*Poliophtila californica*), and Least Bell's vireo (*Vireo billi pusillus*).

Sensitive Species

Protocol and focused surveys were conducted for special-status wildlife species with the potential to occur on the project site. These special-status wildlife species were identified: Cooper's hawk, ashly rufous-crowned sparrow, western yellow warbler, San Diego horned.

Sensitive Non-Federally or State Listed Species

Cooper's hawk is a state Species of Concern and is found in woodland habitats. They were observed onsite throughout the 1998 and 2000 field seasons. Fledglings were commonly observed in lower Devil Canyon during field work in 2000.

Ashy rufous-crowned sparrow is a state Species of Concern and a year-round resident of Southern California. At least three to four pairs of ashy rufous-crowned sparrows were identified on the site primarily near Devil Canyon in 1998, and 2000, with a single observation in the Deer Lake Highlands portion of the site in 1999. No nesting pairs of ashy-rufous crowned sparrow were identified on the site during 1998, 1999, or 2000, but since the birds have been seen in multiple years, it is assumed that some nesting occurs on site.

Western yellow warbler is a state Species of Concern and a migratory songbird nesting in riparian habitats. It was observed sporadically during Spring and Fall migration. Nesting activity was not observed.

San Diego horned lizard is a state Species of Concern. Observed by Envicom Corporation in May and June of 2001.

Federal and/or State Listed Species (Onsite Surveys Conducted With Negative Results)

California red-legged frog was not observed on the project site. It is a federally-listed threatened species that is found from Humboldt, Shasta, and Trinity counties along the western third of the state to the Mexican border. This species is also found along the western slope of the Sierra Nevada range south to Mariposa County. Surveys conducted in Browns and Devil Canyons in 1999 resulted in no observations of this species.

Southwestern willow flycatcher was not observed on the project site. It is a federally and state listed endangered small, migratory songbird found in riparian habitats. The southwestern willow flycatcher breeds from the south end of the Sierra Nevada range to Baja California and east to western Texas. Surveys conducted in 1998 did not result in observations of this species. Focused surveys were repeated in 2000, however the species was not observed.

Coastal California gnatcatcher was not observed on the project site. It is a federally listed threatened species and occurs in many areas of cismontane Southern California from Ventura County to San Diego County. These birds are not common in the vicinity of the project site but have been identified in Simi Valley/Moorpark and in the Sylmar area. Surveys were conducted in 1998 for the coastal California gnatcatcher according to the guidelines issued by the USFWS (1997). During surveys, which covered all areas of coastal sage scrub, no California gnatcatchers were observed on the site. The gnatcatcher surveys were repeated in 2000. This species has not been observed on the site during protocol surveys or at any other time.

Least Bell's vireo was not observed on the project site. It is a federally and state listed endangered small, migratory songbird found in riparian habitats. The Least Bell's vireo was once throughout the Central Valley extending to Baja California. The species has been depleted due to the loss of riparian habitat and the increase in brown-headed cowbird nest parasitism. Protocol surveys conducted in 1998 did not result in observations of least Bell's vireo. Focused studies for this species were repeated in the spring/summer of 2000.

III. OVERVIEW OF PLUMMER'S MARIPOSA LILY

Plummer's mariposa lily (*Calochortus plummerae* ssp. *plummerae*)
 Status: CNPS List 1B R-E-D Code 2-2-3 NDDDB (S3.2) threatened

Literature Reviewed and Status

References used for the description, distribution, and status of the species are: the Jepson Manual, Hichman (ed.), 1993, Wildflowers of the Santa Monica Mountains, McCauley, Rare Plummer's mariposa lily of California, Peggy Lee Fiedler, 1996, interview with horticulturist at Rancho Santa Ana Botanical Garden, 2001, interview with Elana Bengé at Tree of Life Nursery, 2001, interview with David Tibor-Rare Plant Biologist at the California Native Plant Society, 2001, The American Horticulture Society Encyclopedia A-Z of Garden Plants, Christopher Brickwell and Judith D. Zuk (eds.), Growing California Native Plants, Marjorie G. Schmidt, and The Genus *Calochortus* in California: Part II, McDonald, Fremontia 25:1, 1997.

Plant species status is derived from the California Native Plant Society (CNPS) List, which categorizes the relative degree of concern or threat to individual plant species, and the California Natural Diversity Data Base (NDDDB). The R-E-D Code is an assessment of the rarity, endangerment, and distribution of these species. The NDDDB, a program in the Department of Fish and Game, is an inventory of the locations of the state's rarest species and natural communities. The NDDDB (S3.2) status indicated species for which NDDDB has 21-100 reported locations, or 3,000 -10,000 individuals are known, but which are threatened. Plummer's mariposa lily is rare throughout its range. It is judged to be vulnerable under present circumstances or to have a high potential for becoming so because of its limited or vulnerable habitat, its low numbers of individuals per population, and its limited number of populations.

Species Description

Plummer's mariposa lily grows from a tunicated bulb, with a fibrous bulb coat; stems slender, generally branched, not bulbiferous, 30-60 cm high; leaves 2-4 dm long, 10-15 mm wide, usually withered at anthesis; flowers 2-6, bell-shaped, erect, 3 sepals, 30-50 mm, long-tapered; 3 petals, 30-40 mm, white to pink to rose, drying purplish, margin toothed (rarely fringed), long-yellow-hairy in wide central band, nectary round, slightly depressed, bordered with ring of orange hairlike processes; 6 stamens, 3 united carpels from 1 pistil, 3 stigmas, flowers May-July; seed capsules erect, 5-7 cm long, 5-8 mm thick, many seeds in 2 rows per chamber, generally flat, whitish-yellow. Plummer's mariposa lily flowers multiple times from one bulb, but may not flower every year. The bulb may be in a resting state for one to two years.

Habitat Preferences

Plummer's mariposa lily, endemic to California, is found in dry rocky places, often in brush, below 5000 feet. Typical habitat types include coastal sage scrub, chaparral, foothill woodland, and yellow pine forest and valley grassland from the Santa Monica Mountains to the San Jacinto Mountains. It is found in Los Angeles, Ventura, Riverside, and San Bernardino Counties.

Plummer's mariposa lily do well in a light, sandy, porous soil. It is supported by soils derived from sandstone bedrock. This species prefers soil low in organics. Soil samples taken from the Deerlake Ranch Development Project site were analyzed and results indicate that the preferred soil is alkaline with very low levels of nitrogen, potassium, sulfur, boron, and soluble calcium. The pH values range from 7.41 to 7.30. The site where the greatest number of Plummer's mariposa lily is found has a pH of 7.41. The salinity values are low at 0.1 millimho/cm. Low salinity is indicative of low fertility. Besides low fertility, magnesium is high. Magnesium is limiting the uptake of potassium and calcium. Plant growth can occur in infertile soil, but the rate of growth is quite slow. Fertilization is recommended when propagating bulbs and seeds.

IV. PLUMMER'S MARIPOSA LILY SALVAGE, PROPAGATION, AND RESTORATION

If available, a minimum of 4,000 bulbs, or all bulbs uncovered that are located on the project site shall be salvaged and collected prior to grading. Seed shall be collected prior to grading for direct application and use in growing plants at a qualified native plant nursery. Every attempt shall be made to conduct the salvage operation during the appropriate season (late summer /early fall months subsequent to flowering), if feasible. Both short and long-term storage of the bulbs at a qualified native plant nursery shall immediately follow collection. Stored bulbs will serve multiple functions. Bulbs in short term storage shall be replanted directly to locations onsite *that are outside of the fuel modification zone* and to offsite mitigation land(s) in the fall/winter after salvage. The qualified native plant nursery will also propagate seeds and bulbs. Seed shall be collected from the flower of these bulbs for production of new plants. The site-collected and seed-grown bulbs will also serve as a stock to be transplanted at later dates. Bulb stock is necessary to serve as a back up for bulbs that do not survive transplantation and to provide diversity to the preserved sites. Bulbs from the reserve shall be transplanted to appropriate locations each year or bi-annually over a five-year period as determined by a qualified biologist. Plummer's mariposa lily shall be stored at the nursery for 5 years to ensure the success of transplantation. If after 5 years the program is a success (60% survival of out planted bulbs) then the remaining bulbs shall be planted. This plant has been very successful in nurseries in the past and therefore, bulbs are expected to survive for the length of time specified. The percent of total bulbs collected to be used for each purpose is presented below.

- 40% of the bulbs shall be transplanted in the fall/winter following salvage;
- 20% of the bulbs shall be grown for seed collection;
- 40% of the site-collected bulbs shall be used for transplantation over the five-year monitoring period (which may be extended depending on the success of the program); and,
- All seed-grown bulbs shall be transplanted.

Provided below is a step by step outline for undertaking the procedures described above.

Step 1: Salvage of Bulbs Prior to Grading

The applicant shall contract with a qualified, County-approved native plant specialist to salvage the bulbs from the site.

- Prior to the beginning of any grading or scraping operation, collect seed and salvage all flagged and uncovered plants.
- Bulbs shall ideally be salvaged in the course of the summer, but can be successfully salvaged at other times during the year. The preferable time to salvage is after the bulbs have flowered, but this is not crucial to the success of transplantation. A previous project required the salvage to occur during March and the bulbs had a high success rate. Collect seed in late summer to early fall.
- Bulbs shall be placed in a polyethylene bag containing a small quantity of native soil.
- Bulbs and seed shall be stored in a cool, dark location, free from rodent predation, until planted in containers or transplanted. Use of a refrigerator is recommended.
- Salvaged bulbs shall be contract-grown by a qualified native plant nursery.
- A qualified biologist shall monitor all salvage operations.

Step 2: Propagation Technique for Nursery Seed-Collection (20% of total bulbs collected)

All salvaged seeds and bulbs shall be delivered to a qualified native plant nursery for propagation and storage.

Methods for planting seed-collection bulbs

- Bulbs shall be planted in containers in the fall, with onset of cooler weather.
- Bulbs can be individually planted in deep liners (leach tubes), or planted in groups of up to 10 bulbs in one-gallon pots.
- Bulbs shall be planted to depth of 2-4 inches, or at a depth typical of those bulbs salvaged, with pointed end upward.
- The larger bulbs shall be planted the deepest.
- Medium of sterile soil can be amended with bulb fertilizer such as Lily Miller Bulb and Bloom, or 49er Bulb Fertilizer
- Containers shall be placed on benches and protected from rodent predation with wire cage. Rodents will eat the bulb, while deer, grasshoppers, snails, and slugs will eat the foliage.
- Part shade or filtered shade preferable during heat of day. More specifically, ensure that the base of the plant is shaded and the top, especially the flower, is in the sun.
- Watering cycle can be regular (2-3 times per week) through late spring. Water freely when in growth; water sparingly as the leaves die back; provide dry conditions when dormant (summer). Plants should not be watered in summer. If they are, they will rot and not appear the next year.

Collection and Propagation of Seed from site and Nursery Grown Bulbs

Seeds shall be collected from bulbs specified for this purpose. Seed collection shall occur after the plants have flowered and the flowers have dried. Flowering usually occurs between May and July and therefore, seed collection should occur between August and September. A seed collection of Plummer's mariposa lily is a high priority for its successful restoration, and growing these site-collected bulbs in a nursery, and collecting any seed produced can be considered the most reliable method of acquiring this seed.

- Seed shall be contract-grown by a nursery experienced with calochortus propagation.
- Seed collections shall be made from any bulbs that flower. These seed collections can be stored for future propagation.
- No pretreatment of seed necessary due to mild climate of collection site. As explained by Hugh P. McDonald, (Genus Calochortus in California, Part II, Volume 25:1, Fremontia, January 1997) seeds of species from the high mountains or from eastern California may require cold stratification to germinate, whereas the same seeds from a mild climate do not require this treatment.
- Use a light, well-drained, sterile potting soil.
- Fertilizer such as Lily Miller Bulb and Bloom or 49er Bulb Fertilizer shall be incorporated into potting soil. Seed should be planted 1/4 to 1/2 inch under the surface of soil.
- Part shade or filtered shade preferable during heat of day.
- Propagation flats shall be protected from rodent predation.
- Watering cycle can be regular (2-3 times per week) through the late spring. Plants should not be watered in summer.
- Plantlets can be teased-apart into small groups and planted into individual pots when second season of growth has commenced.
- Entering third season, plants should be ready for transplantation to the onsite preserved lily habitat and/or the offsite mitigation property, as appropriate. This shall be determined by a qualified biologist, and may bloom the following spring.

Step 3: Restoration Program (following successful propagation)

Immediate Transplantation of Stored Bulbs

Bulbs salvaged from the site and held in short term storage can be transplanted as soon as the following autumn. The bulbs should not require extensive care from the nursery as long as the transplantation sites are available.

Transplantation of Site-Collected and Nursery Seed-Grown Bulbs

Site-collected bulbs shall be kept in cold storage and transplanted on an annual or bi-annual cycle to the onsite and offsite preserved habitat. For plants grown from seed, a minimum of three years in propagation at a native plant nursery is required. This is necessary to allow sufficient time for the bulbs to grow large enough to produce flowers. After the plants begin to flower they are ready for transplantation.

Timing of Transplantation to the Mitigation Site and/or Onsite Preserved Lily Habitat

The plants should be planted in the fall, with the onset of the cool, rainy season in a soil that contains some moisture. This condition should be best met if the plantings are delayed until a significant rainstorm has moistened the soil of the restoration site. A majority of the bulbs should be in an active state of growth.

Method of Transplantation

The plants can be installed with a deep spade. Soil should be in firm contact with the root ball, not allowing any air pockets to remain. The plants should be planted to the full depth of their containers, while keeping the upper soil level consistent with the final grade of the slope. With the restoration soil moist, no further watering should be necessary.

Management Guidelines

Monitoring

Plummer's mariposa lily shall be monitored closely for a minimum of five years to ensure successful growth. Restoration sites should be investigated in the winter and fall of each year. During the investigation the individual plants will be counted to determine the success rate. Little research has been completed on this species and therefore, it would be beneficial to monitor the plants closely not only to ensure successful growth, but also to document observations for future use. A qualified County-approved biologist shall conduct the monitoring. Additional information including surrounding vegetation and any intrusive weeds observed should be documented as well.

Plummer's mariposa lily does not require a great deal of maintenance. They do not need to be watered at any time during the year. Weed maintenance should be minimal on restoration sites, but the area should be monitored for weeds invasion that could impair the growth of the plant.

Exotic Plant Eradication

The management emphasis is to control exotic, weedy, non-native species within areas populated by Plummer's mariposa lily or areas used onsite or offsite transplantation. While the plan recognizes that complete eradication of exotic plants is unlikely, ongoing maintenance efforts will greatly reduce the cover and type of non-native plants that out-compete Plummer's mariposa lily for light, space, and nutrients.

The process of restoration of Plummer's mariposa lily will require regular monitoring to identify the expected and unknown, however anticipated problem exotic species. For each newly found exotic, weedy species, measures will have to be developed and executed for control on an as-needed basis.

Weeds shall be removed before they produce seed. This will assist in reducing future maintenance efforts, as, if well managed in the transplantation phase, weeds will be out-competed by Plummer's mariposa lily. Hand pulling is the preferred method of control for exotic species. Limited use of selected herbicides, however, can also be employed. All weeded material should be removed from the site. Herbicide is specified for weed species that may re-sprout from roots or rhizomes, or for areas where work crews cannot effectively work.

V. OFFSITE HABITAT PRESERVATION

Mitigation Value

The applicant is committed to undertaking actions that fully compensate for impacts to sensitive biological resources including the lily. Therefore, offsite habitat preservation shall be required in combination with onsite mitigation measures to achieve a less than significant finding to sensitive biological resources under CEQA. The project mitigation approach focuses on the lily as one of the "keystone" species for offsite preservation in conjunction with its salvage, propagation, and transplantation to both suitable onsite and offsite habitat. This combination of habitat preservation and the salvage, propagation, and transplantation of the lily to both onsite open space and purchased mitigation land would effectively reduce impacts to less than significant for this sensitive plant.

In addition, the other "keystone" element of an offsite mitigation property would be the inclusion of riparian willow and oak woodland and coastal sage scrub to compensate for the loss of these habitats with project implementation. The proposed project would remove the total 2.39 acres of coastal sage scrub existing onsite. While the coastal sage onsite is degraded, a 2:1 offsite mitigation ratio (4.78 acres) is recommended given the importance of this habitat to wildlife. The project site also supports 5.73 acres of coast live oak woodland, of this amount 1.30 acres would be impacted by the proposed project. Using a 2:1 mitigation ratio results in the need to preserve 2.60 acres offsite.

In regards to the 9.88 acres of willow scrub/woodland onsite, the proposed project would impact 0.02 acre for grading and 0.01 acre for fuel modification. Using a 4:1 mitigation ratio, a total of 0.12 acre would be required for offsite compensation. In addition, a total of 353 oak trees and one heritage tree exist on the project site. The project proposes removal of 65 oak trees for construction purposes. As the oak trees function as woodland habitat, offsite preservation of 65 existing oak trees (a 1:1 ratio) is recommended. This mitigation would be in addition to the County of Los Angeles Oak Tree Ordinance requirements in order to compensate for the loss of habitat values.

In summary, the offsite mitigation property(s) shall support, at a minimum the following habitat types:

- Plummer's mariposa lily (62 acres of potential and/or occupied habitat);
- Coastal sage scrub- 4.78 acres (represents a 2:1 mitigation ratio);
- Coast live oak woodland – 2.60 acres (represents a 2:1 mitigation ratio);
- Oak trees – 65 trees (represents additional mitigation above that required by the County of Los Angeles to account for impacts to the biological functions of oak trees) and,
- Willow woodland – 0.12 acre (represents a 4:1 mitigation ratio).

In regards to the following sensitive wildlife observed onsite, the project shall implement the measures listed below:

Migratory/Nesting Birds – For both the Cooper's hawk, Ashy rufous-crowned sparrow, Western yellow warbler and for any other nesting bird protected by the Migratory Bird Treaty Act, surveys shall be conducted by a qualified biologist to locate nesting sites. This work shall be completed prior to vegetation disturbance, with one final field investigation immediately before the start of grubbing. If any nesting birds are located, a 100-foot buffer shall be delineated and no disturbance shall occur in this zone until the nestling have fledged.

Cooper's hawk – This species is known to occur in suburban areas that are densely vegetated, thus attracting songbirds, the primary food of the Cooper's Hawk. Therefore, with appropriate native plant landscaping, songbirds should continue to be attracted to the site providing a food source within close proximity of potential nesting areas. With avoidance of the riparian and oak woodland

habitats, no direct impacts on nesting sites are anticipated (trees are the preferred nesting sites of this species and many other hawks found in the area).

Ashy rufous-crowned sparrow - Landscaping of the site shall include native sage scrub (coastal) within common areas that are not subject to fuel modification. This is because the Ashy rufous-crowned sparrow prefers dense vegetation with high cover. In addition, the Devil Canyon area, where they were observed the most, shall be preserved as natural habitat.

Western yellow warbler – Landscaping of the site shall include native plants, including native oaks, cottonwoods, and willows. The trees and native plants attract insects, thus providing a food source for this migratory species. While no nesting activity was observed onsite, preservation and management of the riparian corridor onsite could provide potential nesting opportunities. Therefore, to protect this bird and other species using the riparian areas, no recreational activities including trails, bikes, dog walking, or any other activity that could disturb the use of this area by sensitive species shall be allowed.

Level of Significance after Mitigation

With implementation of the onsite avoidance and minimization measures, in combination with offsite habitat preservation the project impact's to the sensitive biological resources described herein would be reduced to a less than significant level.

Potential Offsite Mitigation Properties

Consultation With Government and Non-Profit Entities

Envicom Corporation has contacted numerous private and public agencies to identify potential preservation sites including the Santa Monica Mountains Conservancy, the Nature Conservancy, the National Park Service, and the Mountains Restoration Trust. Mrs. Roary Skay and Mr. Paul Edleman were contacted at the Santa Monica Mountains Conservancy in June 2001.

The Santa Monica Mountains Conservancy indicated there is a high probability that suitable sites are available for purchase and preservation. Envicom Corporation also consulted with Ms. Melanie Beck at the National Park Service on June 27, 2001 and Mr. Fredrick Schmid of the Mountains Restoration Trust on June 26, 2001.

Surveys of Potential Sites

In addition to researching properties known to the resource agencies and conservation groups, Envicom Corporation conducted surveys of adjacent properties to the north of the site. The purpose of these surveys was to identify locations of the lily and to investigate the presence of other sensitive resources (i.e. riparian habitat). Three potential preservation and transplanted sites for the lily and sensitive resources have been identified at this time. One site supports an extensive riparian woodland.

Two sites contained Plummer's mariposa lily in flower and are consistent with the vegetation and site orientation found in the project area (i.e. south facing slopes). The sites are suitable for both habitat preservation and transplanted because: 1) Plummer's mariposa lily were found onsite; 2) the existence of appropriate soil types; and 3) and other species known to coexist with the lily are present. The habitat on these two properties consist of open chaparral with predominantly chamise and black sage, which is indicative of areas that will support the salvaged bulbs; as well as oak woodland, riparian woodland, coastal sage scrub, and wetland/stream habitat.

APPENDIX H

OAK TREE REPORT

PRELIMINARY OAK TREE REPORT

OBJECTIVES

The objective of this report is to determine the potential impacts from the proposed project on the existing oak trees on the site, for Vesting Tentative Tract No. 53138, Phases I and II and to recommend appropriate mitigation measures. This determination included the following:

1. Determining the conditions of the trees addressed (see the **FIELD OBSERVATION** sheets);
2. Providing guidance to minimize any encroachments upon the saved trees.

OAK SPECIES

The 353 oaks noted in this report are of the species *Quercus agrifolia*, commonly known as the Coast Live Oak.

METHODS of STUDY

Qualifications of the oak trees were done by the work of Poly Associates in 1998; and by L. Newman Design Group, Inc. (LNDG) on February 3, 2000, November 8, 2000 and December 11, 2000. The following tasks were performed:

1. 303 oak trees were tagged with numbered metal tags. These tags are affixed to the side of the tree and correspond to those numbers on the **OAK TREE LOCATION MAP**.
 - A. The oak trees inventoried by Poly Associates are tagged: 1-285 including 263A, 265A, 266A, 267A, 269A, 274A, 279A.
 - B. The oak trees inventoried by LNDG were tagged 1A, 1B, 202A-202G, 261A and 261B.
 - C. Approximately 50 oak trees were found in a 13-acre portion of land that has recently been added to the original site. These were not tagged but were noted on the plan.
2. Live tree trunk diameters of 8" and larger for a single trunk and 12" and larger (of at least two trunks) for a multi-trunk, were measured at 4½' above existing grade, and were assessed for plant quality.
3. The driplines (tree's canopy) were field measured at four compass directions equidistant around the circumference of the tree.

All the inventoried trees were field located on a topographic map (scale: 1"=50'), initially prepared by B&E Engineers, and subsequently transposed onto the tentative tract map also prepared by B&E Engineers. Refer to the enclosed **OAK TREE LOCATION MAPS** herein for the tree locations.

PROJECT LOCATION

This proposed residential development is located in the Chatsworth unincorporated area ("Thomas Guide 2000" page 500 // sections A-1 & B-1) of Los Angeles County, CA.

OAK TREE ORDINANCE

Oak trees (of the genus *Quercus*) within the County of Los Angeles are protected by law. County Ordinances #88-0157, #93-0017, and #93-0018; makes the cutting moving, removal, or encroachment into the Protected Zone of an Oak tree without a permit a misdemeanor. The Protected Zone shall mean that area within the dripline of an Oak tree and extending there from to a point at least 5' outside the dripline, or 15' from the trunk(s) of a tree, whichever distance is greater. The major thrust of the Oak Tree Policy (OTP) was established to recognize Oak trees as significant, historical, aesthetic and valuable ecological resources, and as one of the most

picturesque trees in Los Angeles County, lending beauty and charm to the natural and man-made landscape, enhancing the value of property, and the character of the communities in which they exist. In addition, the OTP intends to create favorable conditions for the preservation and propagation of this unique, threatened plant heritage, particularly those trees which may be classified as 'Heritage Oak Trees', for the benefit of current and future residents of Los Angeles County. It is the intent of the OTP to maintain and enhance the general health, safety, and welfare by assisting in counteracting air pollution, and in minimizing soil erosion and other related environmental damages. The OTP is also intended to preserve and enhance property values by conserving and adding to the distinctive and unique aesthetic character of many areas of Los Angeles County in which Oak trees are indigenous.

If replacements are required, they shall consist of a minimum of two 15-gallon Oak specimens (from Los Angeles, Orange, or Ventura County nursery-grown stock) that measure: 1) at least 1" diameter on a single trunk tree, or 2) a combination of the 2 largest trunks that measure at least 1" diameter on a multiple trunk tree; as measure at 1' above the base.

RESULTS of STUDY

1. Physiological Condition of the Oaks

The physiological condition of trees is detailed in the **FIELD OBSERVATION** sheets contained within this report. All recommendations made on the field forms relate only to the specific dates of the fieldwork.

2. Summary of Data/Plan Review

- A. There are 303 Coast Live Oak trees (**none of which are Heritage Oak trees**) on the project site, which were evaluated as part of this report. There are approximately 50 additional oak trees in the 13 acres recently added to the site.
- B. In order to construct this project 65 Coast Live trees will require removal. The following is a list of the causes for removal. Note: since the time that Poly Associates conducted their field review, the proposed project plan has been revised. However, individual tree characteristics remain unchanged.

C. Drip lines on the **OAK TREE LOCATION MAP** are schematic only (see the **FIELD OBSERVATION** sheets within this report for this information).

3. **Specific Overall Mitigation Recommendations**

- A. In accordance with the above information, the following mitigation is proposed: a minimum of 130 15-gallon Oak specimen trees shall be planted on this site as replacement trees for the 65 required Oak tree removals.
- B. Replacement trees shall be properly maintained for a period of 2 years and replaced by this project developer if fatality occurs during that period.
- C. Oak Tree Planting Plan
 - 1. The Landscape Architect/Designer for this project shall design into the "native undisturbed landscape area" these replacement Oak trees. In "native undisturbed landscape areas", which will be noted on the future "Landscape Architectural Plans" and/or "Restoration Plans", where new nursery grown trees are to be planted, trees may be up to a density of no closer than 20' apart.
 - 2. The irrigation system to water these newly planted replacement trees shall be compatible with the watering requirement of the project's indigenous Oak trees.
- D. Any County approved work within the Protected Zones of the saved Oak trees, including pruning, shall be under the observation of a qualified Arborist.
- E. Copies of the final "Oak Tree Report" and the "Los Angeles County approved Oak Tree Permit" shall be maintained on-site during all site construction.
- F. As development occurs around the saved Oak trees, they will become dependent upon the future residents for their care and preservation. All construction activities shall be conducted in accordance with the following established **PRESERVATION PROGRAM**. This program was developed to control the impacts to each tree and to protect them from any unnecessary and unscheduled damage. All Oak tree mitigation techniques shall be observed on-site by of a qualified Arborist. The following list of recommendations, if followed, should insure that the saved Oak trees would remain as valuable assets to the community.

1. **Tree Protection**

- a. The trees within 50' of proposed grading shall be fenced at their "Protected Zones", or at the location of their approved encroachment, with a minimum 4' high chainlink fence, or an acceptable alternative, before any site grading commences. No equipment storage, debris drip, etc., shall take place within any tree Protected Zone. This fence shall not be moved and/or removed without certification from a qualified Arborist and approved by the Los Angeles County Forester.
- b. Any brush clearance within the driplines shall be completed by handwork only.

2. **Dead Wood Removal and/or Pruning** (only if needed)

- a. Dead wood removal is the removal of dead wood from within the tree, while structural pruning for clearance and/or safety pruning of hazardous limbs should only be done if approved by the Los Angeles County Forester. All pruning shall

- b. be done by a qualified Arborist on an "as needed basis" and is subject to the approval by the Los Angeles County Forester.
 - b. Pruning wounds shall not be sealed unless required by the Los Angeles County Forester.
 - c. Climbing "gaffs" shall not be used by any tree climber except to reach an injured climber or when removing a tree).
3. **Water & Fertilization** (only if needed)
- a. The water and fertilization frequency shall be done on an "as needed basis" and is subject to the approval of the Los Angeles County Forester.
 - b. Native Oak trees are in a dormant state during the summer months and do not require regular or constant watering (or fertilizing). Watering is normally contemplated only following long periods of extreme drought.
 - c. Fertilization of these native oak trees may be detrimental in general drought conditions. The addition of fertilizer into a maintenance program may promote temporary growth "flushes" at a time when the tree would normally be maintaining regular growth or to even reduce the number of green leaves present. The greater amounts of foliage the tree has the higher the needs of watering requirements may occur.
4. **Disease & Pests** (only if needed)
- a. During all phases of construction, the health of the trees shall be monitored by a qualified Arborist for signs & symptoms of disease. These problems, if they arise, shall be remedied as prescribed.
 - b. If bees are encountered and they become a problem in any on-site oak trees, they shall be removed by a professional beekeeper.
5. **Grading within the Protected Zone**
- a. No grading shall take place within the Oak tree Protected Zones without the approval of the Los Angeles County Forester. If grading is approved within the Protected Zone, a qualified Arborist **shall** be present during all work. This shall initially be done by handwork.
 - b. All pruned roots shall consist of clean-cut surfaces at a 90° angle and shall not be sealed unless approved by the Los Angeles County Forester.
6. **Other Considerations**
- a. As reference material, refer to the leaflet (P09-88) titled "Oak Tree Care and Maintenance," as prepared by the Los Angeles County Fire Department – Forestry Division.
 - b. **Do Not:** 1) Nail grade stakes or anything else to any native Oak tree; 2) Remove natural leaf mulch within any native Oak dripline, unless absolutely necessary; and/or, 3) Apply herbicides within the Protected Zone of any native Oak tree.

- b. The dust accumulation on the tree's foliage (from nearby construction) shall be hosed off during construction, under the advice from a qualified Arborist.

NOTICE of DISCLAIMER

The report represents the independent opinion of the signatory consultant (L. Newman Design Group, Inc.). The trees discussed herein were generally reviewed for physical, biological function and aesthetic conditions. This examination was conducted in accordance with presently accepted industry procedures, which are a ground-plane macro-visual observation only. No extensive micro-biological, soil-root excavations, upper crown examination nor internal tree investigations were conducted and therefore, the reporting herein reflects the overall visual appearance of the trees on the date reviewed and no warranty is implied as to the potential failure, health or demise of any part of or whole of any tree described in the report. Records may not remain accurate after our inspection due to unknown causes of changeable deterioration of the reviewed site.

Respectfully Submitted,

L. Newman Design Group, Inc.

OAK TREES:
Care and Maintenance
(Leaflet P09-89, prepared by LACFD-FD)

OAK TREES: Care and Maintenance

This Oak Tree Care and Maintenance Guide offers basic information and practical guidelines aimed at the preservation and continued health and survival of oak trees in the residential landscape.

Increasing pressure for development is changing the Oak Woodlands of Los Angeles County. Heritage oaks which once survived in open rolling hills are now being preserved or replanted and incorporated into the community.

How do we protect these trees during the planning and development process, and insure their survival once they are in the home garden?

The Oak Tree

Oak trees in the residential landscape often suffer decline and early death due to conditions that are easily preventable. Damage can often take years to become evident, and by the time the tree shows obvious signs of disease it is usually too late to help.

Improper watering, especially during the hot summer months, and disturbance to critical root areas are most often the causes. This booklet will provide guidelines on where these critical areas lie and ways to avoid disturbing them, as well as information on long term care and maintenance of both natural and planted oaks. Lists of additional resources for more information and demonstration areas to visit are also included.

The Oak Tree Ordinance

The Los Angeles County Oak Tree Ordinance has been established to recognize oak trees as significant historical, aesthetic, and ecological resources. The goal of the ordinance is to create favorable conditions for the preservation and propagation of this unique and threatened plant heritage. By making this part of the development process, healthy oak trees will be preserved and maintained.

The Los Angeles County Oak Tree Ordinance applies to all unincorporated areas of the County. Individual cities may have their own ordinances, and their requirements may be more stringent.

Permit Requirements:

Under the Los Angeles County Ordinance, a person shall not cut, destroy, remove, relocate, inflict damage, or encroach into the *protected zone* (see text) of any tree of the oak tree genus without first obtaining a permit.

Damage includes but is not limited to:

- burning
- application of toxic substances
- pruning or cutting
- trenching
- excavating
- paving
- operation of machinery or equipment
- changing the natural grade.

Section 22.56.2050: Oak Tree Permit Regulations, Los Angeles County.

Date of Adoption: September 13, 1988

For more information on the Oak Tree Permit, contact:

The Los Angeles County Dept. of
Regional Planning
320 W. Temple Street
Los Angeles CA 90012
(213) 974-6401

Types of oaks commonly found in Los Angeles County:

Many kinds of oak trees are native to Los Angeles County. A few of the more common ones are shown below, but *all* oak trees are covered by the oak tree ordinance.

Older oaks which have thrived under the natural rainfall patterns of dry summers and wet winters often can't handle the extra water of a garden setting. These trees must be treated with special care if they are to survive.

Those oaks that have been planted into the landscape or sprouted as volunteers tend to be more tolerant of watered landscapes. While these vigorous young trees may grow 1 1/2 to 4 feet a year in height under good conditions they are not as long-lived. Once established these trees would benefit from the same special care outlined in this guide.

Valley Oak

QUERCUS LOBATA

LARGE DECIDUOUS TREE 60'-75' HIGH, BROADLY SPREADING 50'-80' WIDE.

LEAVES: DEEP GREEN, 3"-4" LONG; PAPER-LIKE TEXTURE WITH DEEP ROUNDED LOBES ON THE LEAF EDGE.

TENDS TO FAVOR VALLEY BOTTOMS; FOR THIS REASON THE VALLEY OAK HAS DISAPPEARED FROM THE LANDSCAPE MORE RAPIDLY, IMPACTED SEVERELY BY AGRICULTURE AND URBAN DEVELOPMENT.

Coast Live Oak

QUERCUS AGRIFOLIA

LARGE EVERGREEN TREE WITH A BROAD, ROUND SHAPE AND LARGE LIMBS. 30'-70' HIGH, 35'-80' WIDE.

LEAVES: GLOSSY GREEN, 1"-3" LONG; SPINY, ROUNDED, AND HOLLY-LIKE; BUT DISTINCTLY CUPPED OR CURLED UNDER AT THE EDGES.

Interior Live Oak

QUERCUS WIGLIZENII

EVERGREEN TREE 30'-75' HIGH OR A SHRUB 8'-10' HIGH IN CHAPARRAL AREAS. HAS A FULL, DENSE ROUNDED SHAPE, NOT BROAD OR WITH LARGE LIMBS LIKE A COAST LIVE OAK. THEY TEND TO GROW IN CLUMPS RATHER THAN AS A SINGLE TREE.

LEAVES: DARK GREEN, 1"-4" LONG. EDGES EITHER SMOOTH OR SPINY, BUT ALWAYS FLAT— NOT CURLED UNDER.

OTHER COMMON OAKS:

CALIFORNIA BLACK OAK: QUERCUS KELLOGGII

CANYON LIVE OAK: QUERCUS CHRYSOLEPIS

ENGELMANN OAK: QUERCUS ENGELMANNII

THE PROTECTED ZONE

The *protected zone* defines the area most critical to the health and continued survival of an oak tree. Oaks are easily damaged and very sensitive to disturbances that occur to the tree or in the surrounding environment.

The root system is extensive but surprisingly shallow, radiating out as much as 50 feet beyond the spread of the tree leaves, or *canopy*. The ground area at the outside edge of the canopy, referred to as the *dripline*, is especially important: the tree obtains most of its surface water and nutrients here, as well as conducts an important exchange of air and other gases.

The protected zone is defined in the Oak Tree Ordinance as follows:

"The Protected Zone shall mean that area within the dripline of an oak tree and extending therefrom to a point at least 5 feet outside the dripline or 15 feet from the trunk, whichever distance is greater."

CONSTRUCTION ACTIVITY WITHIN THE PROTECTED ZONE

Changes in Grade

Any change in the level of soil around an oak tree can have a negative impact. The most critical area lies within 6' to 10' of the trunk; no soil should be added or scraped away. Water should drain away from this area and not allowed to pond so that soil remains wet at the base.

Retaining walls designed to hold back soil above or below an existing tree should be avoided if at all possible, especially within the protected zone. These types of structures cause critical areas at the dripline to be buried, or require that major roots be severed. Water trapped at the base of the tree could lead to root rot or other impacts, and to the decline and premature death of a highly valued landscape tree.

Construction activities outside the protected zone can have damaging impacts on existing trees. Underground water sources can be cut off due to falling water tables, or drainage may be disrupted.

Trenching

Digging of trenches in the root zone should be avoided. Roots may be cut or severely damaged, and the tree can be killed.

If trenches must be placed within the protected zone, utilities can be placed in a conduit which has been bored through the soil, reducing damage to the roots. Insist that as many utilities as allowed be placed in a single trench, instead of the common practice of digging a separate trench for each individual line.

Trenching can also be accomplished using hand tools or small hand held power equipment to avoid cutting roots. Any roots exposed during this work should be covered with wet burlap and kept moist until the soil can be replaced.

Soil Compaction and Paving

The roots depend upon an important exchange of both water and air through the soil within the protected zone. Any kind of activity which compacts the soil in this area blocks this exchange and can have serious long term negative effects on the tree.

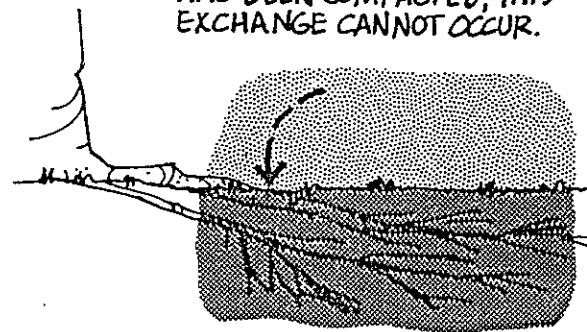

If paving material must be used, some recommended surfaces include brick paving with sand joints, or ground coverings such as wood chips (note the advantages of natural materials for providing nutrients under *mulching*).

SOIL COMPACTION

BOTH AIR AND WATER ARE EXCHANGED THROUGH THE SOIL TO THE ROOTS.

HOWEVER, IF THE SOIL HAS BEEN COMPACTED, THIS EXCHANGE CANNOT OCCUR.

INSIDE THE TRENCH, PLACE UTILITY CONDUIT BETWEEN OR UNDERNEATH MAJOR ROOTS.

MAINTENANCE

Watering

The key is prevention – *do not overwater*. Improper watering is often overlooked as the cause of tree death because it can take years for the damage to show. Once the tree shows obvious signs of decline, it is often too late to correct the problem.

The seasonal weather pattern for this region is one of dry summers and winter rain. Oak trees are naturally drought tolerant and adapted to this cycle. If the tree is vigorous and thriving it should not require any additional water.

If the natural source of surface or underground water has been altered, some supplemental water may be indicated, but proceed with caution. The goal of any watering schedule for oak trees should be to supplement natural rainfall and it should occur only when the tree would normally receive moisture. This might be in the winter, if rains are unusually late, or in spring if rainfall has been below normal levels.

Overwatering, especially during the summer months, causes a number of problems which can lead to decline and eventual death of the tree. It creates ideal conditions for attacks of Oak Root Fungus by allowing the fungus to breed all year. In addition, both evergreen and deciduous oaks grow vigorously in the spring and naturally go dormant in the summer. Extra water only encourages new tip growth which is subject to mildew. Oaks need this period of rest.

Newly planted oaks may need supplemental watering during their first few summers. After they become established water should be applied according to the previous guidelines.

Pruning

For oak trees, the periodic removal of dead wood during periods of tree dormancy should be the only pruning needed. Any cutting of green wood opens scars that could allow the entry of organisms or disease.

Before pruning obtain the advice of a certified arborist or other professional and consult the local city or county where the tree is located to find out what regulations apply. Pruning of both live and dead wood can sometimes require a permit.

Mulching

Leaf litter from the tree is the best mulch and should be allowed to remain on the ground within the protected zone. Crushed walnut shells or wood chips can be used, but the oak leaves that drop naturally provide the tree with a source of nutrients. Avoid the use of packaged or commercial oak leaf mulch which could contain oak root fungus. Redwood chips should not be used due to certain chemicals present in the wood.

Diseases and Pests

Trees that are stressed, especially because of improper watering practices, are prone to certain diseases and attacks by pests.

The most damaging of these diseases is the Oak Root Fungus *Armillaria mellea*. Occurring naturally in the soil, the fungus thrives under wet conditions and dies back in the summer when soils dry out. This is why summer watering of oaks can be a deadly practice. As noted in the watering guidelines, wet soil in the summer allows the fungus to grow all year. As the population grows, their natural food sources are depleted and they begin feeding on oak tree roots. The fungus does not require an open wound in the tree to gain entry.

Indications of the fungus include:

- die back of branches or tips.
- honey colored fungus at or near the root crown.
- white fan-like fungus between the bark and wood.
- the presence of black, shoestring like growths in the soil.

Once the tree begins to show obvious signs of infection treatment is generally ineffective. The best treatment is to *avoid* the conditions that lead to oak root fungus infections.

Pit Scale, Oak Moth, and other pests: any significant changes in leaf color, branch die back, presence of black sooty materials on leaves or other changes should be noted. Seek the advice of a professional forester, arborist, farm advisor or other expert before spraying any pesticides on an oak tree.

Planting Underneath Oaks

The natural leaf litter is by far the best ground cover within the protected zone. If plants must be placed, the following guidelines should be followed:

There should be no planting within a minimum 6 to 10 feet of the trunk.

Avoid plants that require any supplemental water once established.

Choose plants suited for "dry shade." Those listed in the box below offer some good choices. To see some examples of how these plants have been used under oaks refer to the Additional Resources section on the following page.

PLANTS TO CONSIDER:

Plant Name	Description
<i>Arctostaphylos densiflora</i> 'Howard McMinn' Manzanita	3' high, 6' wide. Toughest of available forms. Whitish-pink flowers.
<i>Arctostaphylos edmundsii</i> Little Sur Manzanita	1-2' high, 4-5' wide. Tolerant of full shade.
<i>Arctostaphylos hookeri</i> Monterey Carpet Manzanita	1-2' high, spreading to 12' wide by rooting branches. White to pink flowers.
<i>Ceanothus griseus horizontalis</i> Carmel Creeper	Less than 2 1/2' tall, low and creeping. Clusters of small blue flowers.
<i>Heuchera</i> Coral Bells	2-4' mound. Flowers on an upright stem 2-3" high and spotted with red or pink.
<i>Mahonia aquifolium compacta</i> Oregon Grape	2-4' high, spreading by underground roots. Bright yellow flower clusters.
<i>Ribes viburnifolium</i> Evergreen or Catalina Currant	2-3' high, spreading to 12' wide. Flowers pink to red in small clusters.

NOTES:

Before deciding on plants, check a source such as the *Sunset Western Garden Book* to determine which plants will grow in your area.

When choosing shade tolerant plants, consider that the ground under the south side of the tree will get more sunlight. In this hemisphere the sun stays lower in the southern sky all year, causing the tree to block the light. This causes the northern side to stay in deeper shade.

DEFINITIONS

SUMMARY of FIELD OBSERVATIONS DEFINITIONS

INTRODUCTION

There are numerous diseases and insects, which frequently attack the Oak trees in Los Angeles County. A long discourse in plant pathology or entomology is not necessarily a prerequisite to develop a basic understanding of the casual effects of disease and insects upon living plant tissue. A basic knowledge of disease and insects should include an understanding of the following definitions:

FORM

1. **Tree Number** - each tree in the field (sizes within the existing ordinance) has been assigned a number, which corresponds to a tree location on the "Tree Location Map".
2. **Species** - is the type of tree that is being evaluated.
3. **Number of Trunks** - as measured in accordance to the ordinance existing at the time of evaluation.
4. **Diameter of Trunks** - as measured at 4½' above mean natural grade.
5. **Tree Height** - is the approximate height of each numbered, evaluated tree.
6. **Leaning** - is the direction the tree is inclined from the natural vertical position.

PHYSICAL CONDITION

1. **Trunk Cavity/Damage** - A **Cavity** is a hollow area in the trunk, usually due to wood decay. **Damage** is a damaged area on the trunk, usually due to an external force onto the tree.
2. **Exposed Roots** - roots exposed near tree; e.g. in creek bed.
3. **Exfoliating Bark** - the flaking off of bark from trunk, branches and/or twigs.
4. **Water Pocket** - pockets formed at branch crotches that can hold water and possibly weaken the tree's structure (possible hazard).
5. **Exudation** - the issuance or expelling of liquid, usually from wounds.
6. **Fruiting Bodies** - are the external signs (i.e. mushrooms, conks) of internal wood decay.
7. **Insect/Mite Damage** - is some form of damage to the parts of the tree caused by insects or mites (i.e. scale, caterpillars, weevils, borers, mites, etc.).
8. **Galls/Oak Pit Scale** - **Galls** are abnormal growth (tumors) on the tree, which may be caused by insects, mites, bacteria, etc. **Oak Pit Scale** has a severe weakening effect on the twigs, frequently resulting in their death. When the scale settles on the twig, a swelling of the twig tissue occurs so the insect in effect is in a pit; hence, the name.
9. **Fire Damage** - each tree is rated on the amount of burn it has received. Below are the ratings.

<u>Category</u>	<u>Percent of Tree Burned</u>
Slight (S)	0% - 25%
Moderate (M)	26% - 75%
Heavy (H)	76% - 100%
Complete (C)	Burned to the ground

DEFINITIONS

Los Angeles County

Page 2 of 4

- A. A check mark only, indicates a sign of past fire damage;
 - B. The trees with slight damage have an excellent chance of recovering to their original form. Trees with moderate damage have a good chance of recovery with alterations in form. Heavy percentage of burn on trees will significantly alter their form and lower their probability of survival to half;
 - C. The complete category is those trees, which burned to the ground.
- 10. **Mainstem Dieback** - death of healthy mainstems from the growing tip back.
 - 11. **Branch Cavities** - hollow areas in the limbs, usually due to the decay of wood.
 - 12. **Weak Crotches** - poorly formed branch attachments.
 - 13. **Twig/Branch Dieback** - death of unhealthy twigs from the growing tip back.
 - 14. **Exocormic Growth** - excessive growth along main limbs, rather than on twigs.
 - 15. **Thin Foliage** - defoliation and twig dieback throughout the canopy.
 - 16. **Vigor** - is the capacity of a tree for growth and survival. Below are the ratings:

Good (G) - New tip growth; good leaf color; relatively smooth bark free from cracks/decay;
OK (OK) - Some new tip growth; medium leaf color; some dead wood; thinning crown;
Poor (P) - No new tip growth; poor leaf color; much dead wood; heavily thinned crown.
A vigorous tree will more easily ward off disease and/or insect attacks, and should recover from impacts more quickly than a weak tree.
 - 17. **Terrain** - refers to "lay" of the land where the tree is found.
 - 18. **Potential Hazard** - any tree may be a hazard to humans, depending on its location and/or health.

RATINGS

- 1. A **Heritage Tree** according to the Los Angeles County "Oak Tree Ordinance" is either of the following:
 - A. Any Oak tree that has at least one trunk that is at least 36" in diameter or larger as measured at 4½' above mean natural grade;
 - B. Any Oak tree having a significant historical or have cultural importance to the community, notwithstanding that the tree diameter is less than 36" in diameter (as identified officially by the local Los Angeles County Resource Conservation District).
- 2. The **Health** of the trees was visually determined from a macroscopic inspection of signs and symptoms of disease. The following system was used to describe their conditions:
 - A. **Outstanding** - A healthy and vigorous tree characteristic of its species and free of any visible signs of disease or pest infestation;
 - B. **Above Average** - A healthy and vigorous tree. However, there are minor visible signs of disease and pest infestation;
 - C. **Average** - Although healthy in overall appearance, there is a normal amount of disease and/or pest infestation;
 - D. **Below Average/Poor*** - This tree is characterized by exhibiting a greater degree of disease and/or pest infestation or structural instability than normal and appears to be in a state of decline. This tree also exhibits extensive signs of dieback.
 - E. **Dead*** - This tree exhibits no signs of life whatsoever at the time of field evaluation.

DEFINITIONS

Los Angeles County

Page 3 of 4

*A tree rating of "D" and lower is in a low stage of vigor and naturally a meaningful level of recovery is doubtful. Removal should be considered if it is within the proposed project development.

3. The **Aesthetic/Conformity** quality of the trees was visually determined from an overall inspection of appearance. The following system was used to describe their conditions:
 - A. **Outstanding** - The tree is visually symmetrical, having the ideal form and appearance for the species;
 - B. **Average** - The tree, though non-symmetrical, has an appealing form for the species with very little dieback of foliage or twigs/branches;
 - C. **Below Average** - The tree is non-symmetrical for the species with an unappealing form and/or has much dieback of foliage and twigs/branches;
 - D. **Poor** - The tree has few, if any, positive characteristics and may detract from the beauty of the landscape.

TREATMENT

1. **Remove Dead Wood** - if noticeable dead wood is within the canopy, it should be removed.
2. **Remove Wire, etc.** - if anything has been attached to the tree, it should be removed.
3. **Insect/Disease Treatment** - see TREE PRESERVATION PROGRAM within this report for explanation.
4. **Cable/Brace** - can extend the time the tree remains healthy, attractive and hazard free.
5. **None** - no treatment is recommended.
6. **Remove Tree** - if the tree cannot be saved through any type of treatment, it should be removed.

REMARKS (Some other terms that may be used)

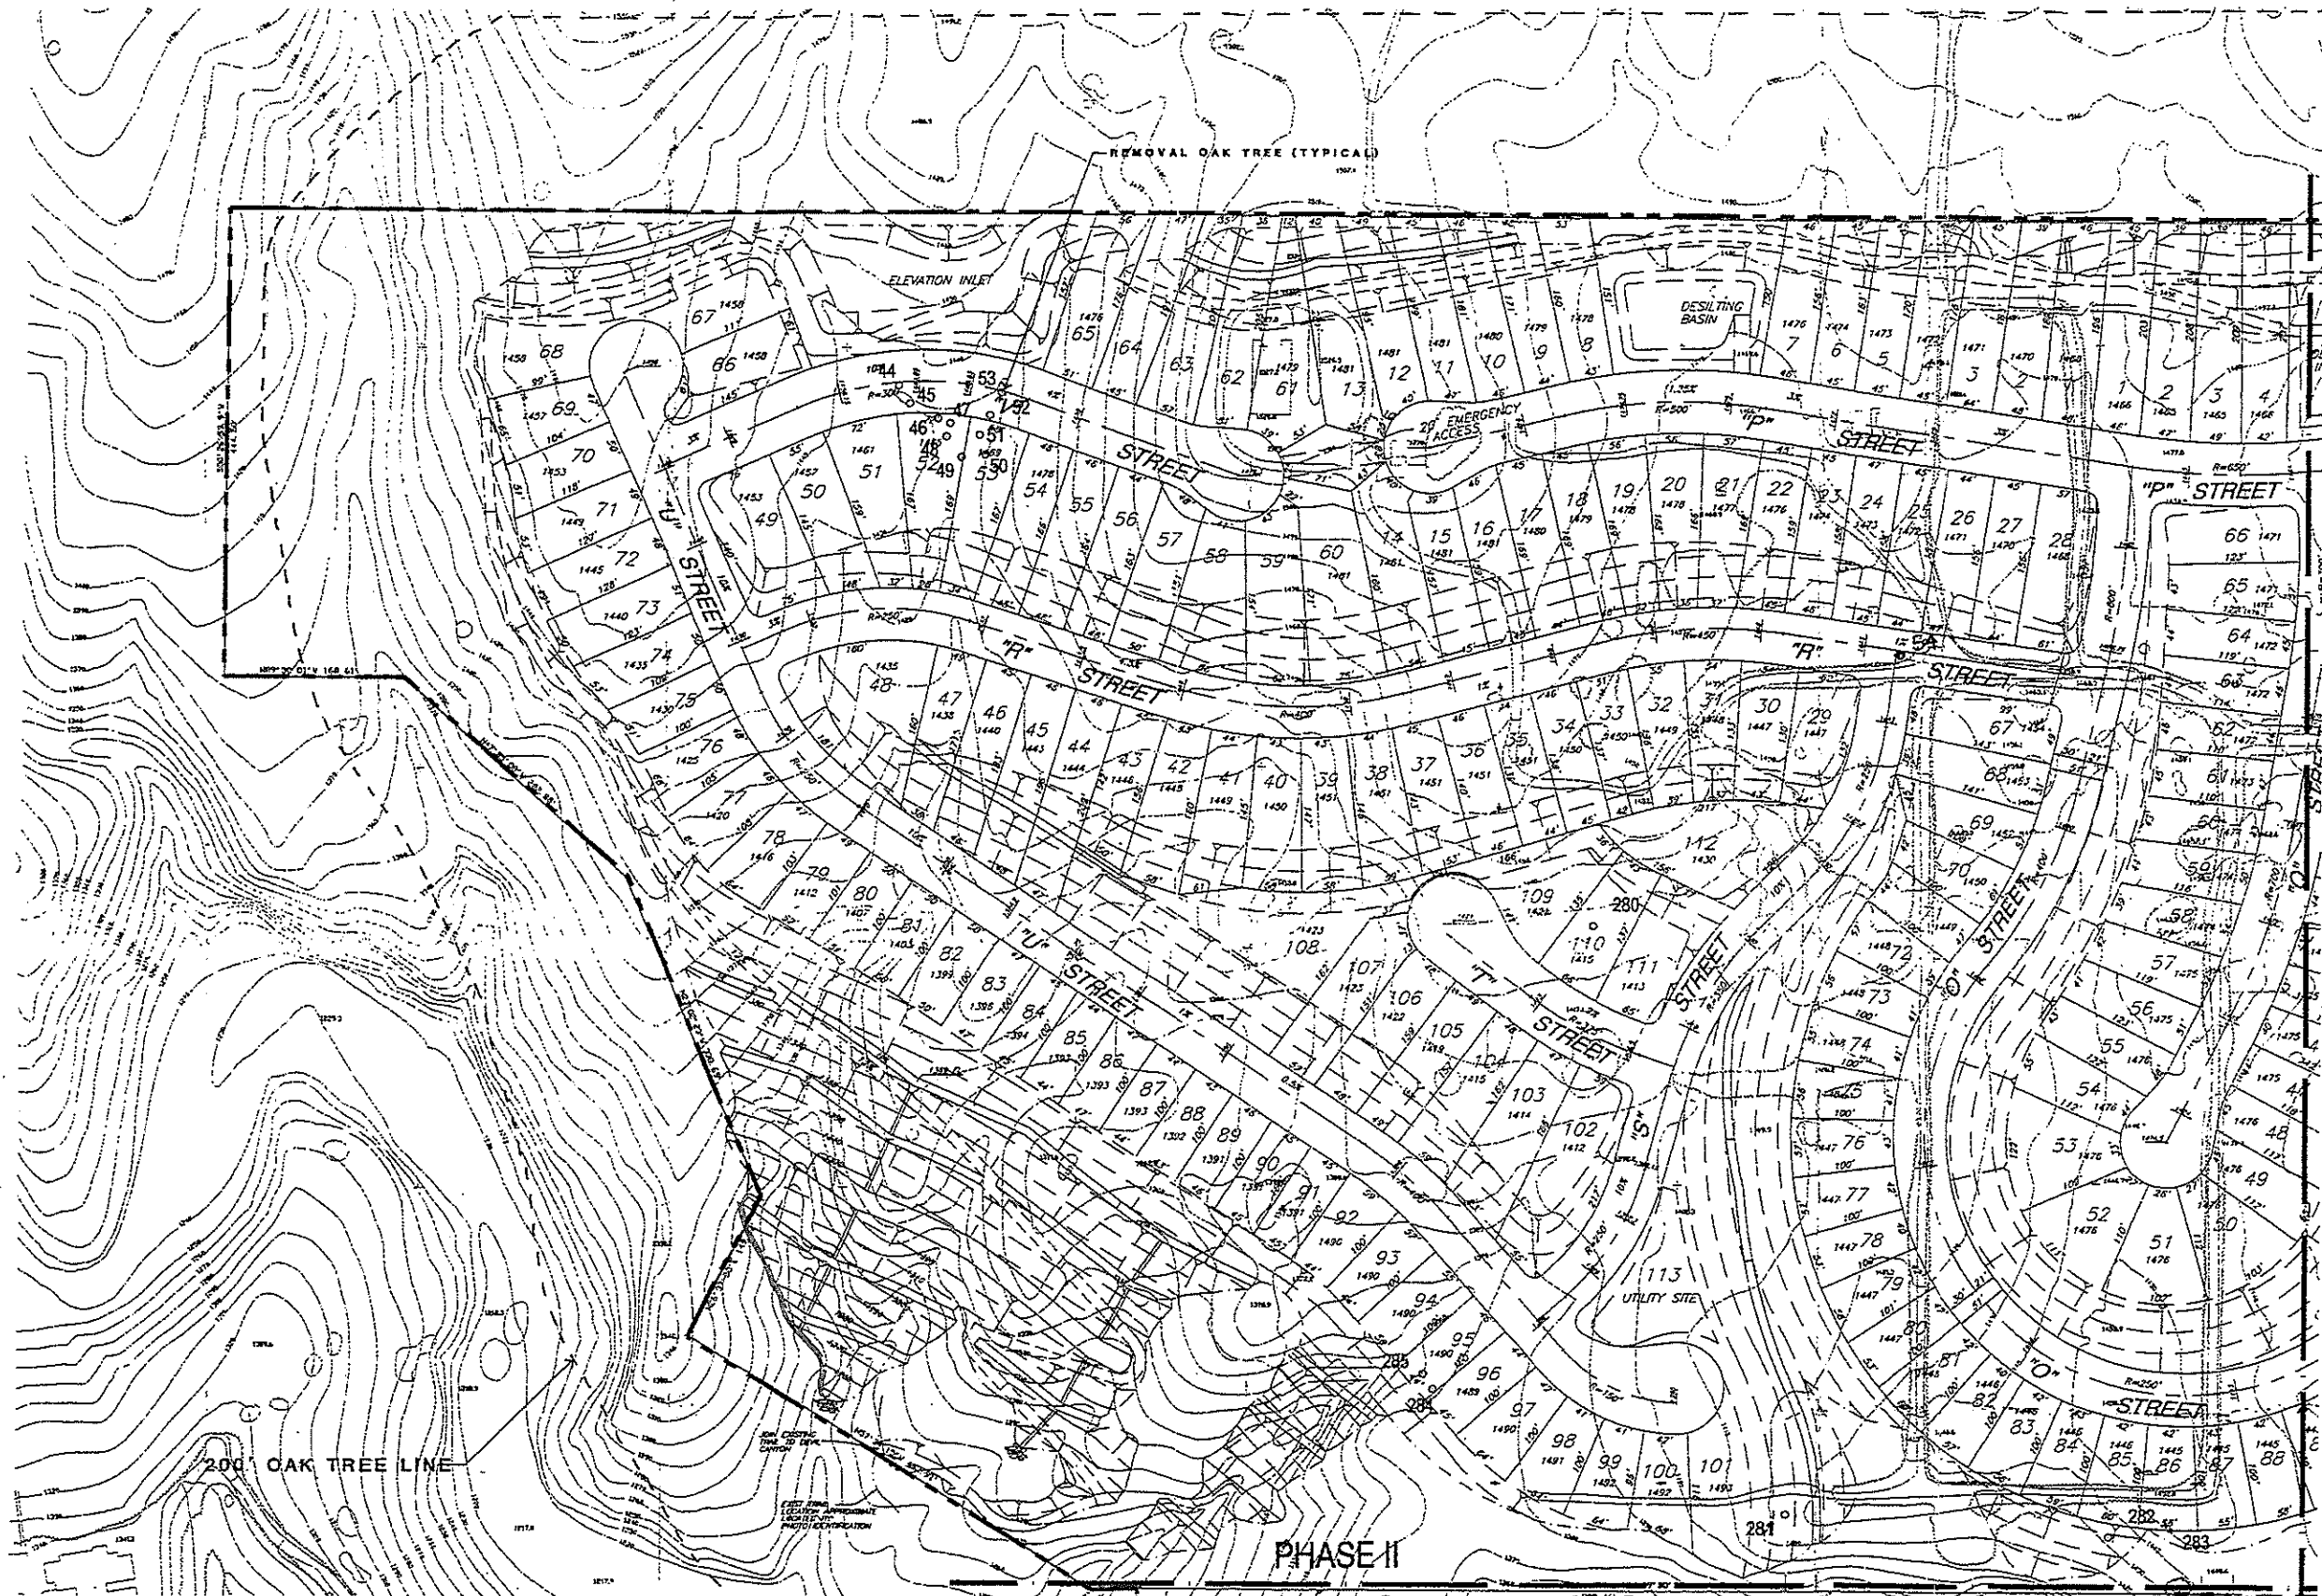

1. **Basal Growth** - is leaf growth generating from around base of trunk.
2. **Exposed Buttress Roots** - is when soil absent, either all or partial, at the tree's base.
3. **Heart Rot** - is decomposition of heartwood (the central portion of a twig/branch/trunk).
4. **Powdery Mildew** - are leaves that are covered by a white powdery growth generally when new growth becomes wet for long periods of time; leaves may be distorted, stunted and drop prematurely.
5. **Cankers** - are rough swellings with depressed centers resulting in death of tissue, which later cracks open and exposes the wood underneath in twigs, branches, and/or trunks.
6. **Chlorotic Leaves** - leaf veins remain normally green, but the tissue between veins becomes yellow, which is usually caused by nutrient deficiencies.
7. **Mottling** - are leaves that have a variegated pattern of green and yellow.
8. **Defoliation** - is a premature leaf drop.
9. **Bark Beetle Frass** - are wood fragments mixed in the insect's excrement.
10. **Witches Broom** - is an abnormal growth cluster of twigs, which may be caused by insects, mites, fungus, etc.

DEFINITIONS
Los Angeles County
Page 4 of 4

11. **Mistletoe** - is a leafy evergreen perennial parasite with dark green leathery leaves that occur as bunches on the branches.
12. **Crowded** - is a tree within the canopy of an adjacent tree or canopy.
13. **Shading Out** - is the defoliation and twig dieback inside the canopy due to the lack of sunlight.

Management Summary

An intensive Phase I archaeological survey was conducted for the 238.8 acres Chatsworth Ridge Estates study area, Los Angeles County, California. This involved background studies of the prehistory, ethnography and history of the area; an archival records search of relevant maps, site forms and documents; and an on-foot survey of the subject property. Eight archaeological sites had been previously recorded on the property, designated CA-LAN-209, -649, -1740H, -1741H, -1742H, -1743, -1744 and -1745. These were relocated and evaluated and, with the exception of CA-LAN-1741H and -1742H, were found to be intact and potentially significant. So-called historical sites CA-LAN-1741H and -1742H, recorded in 1990, appear to be post-World War II in age and consist of the foundations of demolished structures with associated trash and debris, all of which is contemporary. It is uncertain whether these localities meet the minimum age criterion for consideration as cultural resources but, in any event, they do not have any known archaeological value, lack architectural integrity and therefore are not considered significant.

In addition to these eight sites, two newly discovered prehistoric sites were recorded within the study area, given the temporary designations of W&S-1 and -2. Development within the Chatsworth Ridge Estates study area, therefore, has the potential to result in adverse impacts to cultural resources. It is recommended that Phase II test excavations and determinations of site significance be conducted on the eight intact and potentially significant sites within the study area (that is, on sites CA-LAN-209, -649, -1740H, -1743, -1744 and -1745, and W&S -1 and -2), and that final recommendations for the management of these sites be based on the results of these test studies.

1.0 INTRODUCTION

At the request of Mr. Richard Garlinghouse, The Presidio Group, LLC, a Phase I archaeological survey was conducted for the Chatsworth Ridge Estates study area. This approximately 238.9 gross acres parcel lies within the northwestern limits of the San Fernando Valley, Los Angeles County, California (Figure 1). This cultural resources study was conducted by W & S Consultants, with David S. Whitley, Ph.D., serving as principal investigator.

The purpose of the study was to evaluate the potential for the proposed development to result in adverse impacts to cultural resources. It involved background studies of published and unpublished articles, books, manuscripts, maps, drawings and photographs, as well as archaeological site records and files, to establish the prehistory and history of the study area, to determine whether sites had been previously recorded or were known to exist within it. Aspects of the background studies were conducted by the UCLA Archaeological Information Center (AIC), concerning archaeological site files, in addition to the research conducted by W & S Consultants.

This manuscript constitutes a report on this Phase I survey. Following a description and location of the proposed project, the second chapter reviews local prehistory, ethnography and history, with particular emphasis on the land-use history of the study area area. The next chapter summarizes the archival record search conducted by the UCLA AIC. This is followed by the details of an on-site intensive survey of the property in question. We conclude with recommendations for the treatment of cultural resources within the study area.

1.1 Description and Location of the Study Area

The proposed project consists of the construction of suburban housing on an approximately 238.8 gross acres parcel located in the northwestern portion of the San Fernando Valley (figure 1). The study area is located

north of the Simi Valley Freeway (Highway 118), with the southwestern corner of the property at the intersection of this highway and Topanga Canyon Boulevard. This places it within the southern foothills of the Santa Susana Mountains.

The study area can be described as a moderately-sized mesa, the Deer Lake Highlands, that overlooks the western San Fernando Valley, to the south. Browns Canyon, on the east, and Devil Canyon, to the west and south, are the approximate limits of the study area in these directions. Roughly the northern half of the study area consists of the flat mesa-like area, with elevation ranging from about 1300 to 1400 feet a.s.l. However, the steep slopes of the two canyons are included in the eastern, southern and western edges of the study area, where steep slopes exceed the angle of repose. Although some sandstone outcrops are present in the northern half of the study area, the majority of them, understandably are located along this steep peripheral zone.

Historic and recent land-use changes have altered the environment somewhat from what existed in the study area during prehistoric times. At least four major plant associations probably characterized the region containing the study area during the aboriginal period, however. These are chaparral, coastal sage scrub, southern oak woodlands, and riparian associations (cf. Muntz 1974).

The chaparral association covers steeper slopes with poorly developed soils and xeric conditions. It includes the following species: California sagebrush (*Artemisia californica*), white sage (*Salvia apiana*), black sage (*S. mellifera*), purple or white-leaved sage (*S. leucophylla*), California encelia (*Encelia californica*), California buckwheat (*Eriogonum fasciculatum*), scrub oak (*Quercus biberidifolia*), toyon (*Heteromeles arbutifolia*), mountain mahogany (*Cercocarpus betuloides*), lemonade sumac (*Rhus integrifolia*) and sugar sumac (*R. ovata*).

The coastal sage scrub community is the climax community for portions of inland coastal-southern California. It is generally composed of coast buckwheat (*Eriogonum cinereum*), although this species is absent in some of the inland valleys, and California buckwheat (*E. fasciculatum*), along with black sage (*Salvia mellifera*), sawtooth goldenbrush (*Hazardia*

squarrosa), prickly phlox (*Leptodactylon californicum*), yucca (*Yucca* spp.) and California sagebrush (*Artemisia californica*) as major constituents.

The chaparral and coastal sage scrub communities are still present on the slopes of the study area, and were undoubtedly of subsistence importance to the aboriginal population of the region, the third association, the southern oak woodland, may have been of primary significance in the inland zones adjacent to the coastal strip. This results because of the great importance placed on the acorn as a food staple by Native Californians (Kroeber 1925), and the rarity of this resource on the coastal side of the Santa Monica Mountains. The association is characterized by the coast live oak (*Quercus agrifolia*) and the valley oak (*Q. lobata*), but also would have included various species of native grasses. Although currently restricted in distribution, this association was once more widespread in the region. The open flats of the San Fernando Valley in fact, were once partly covered by oak woodland, and it is possible that the mesa-like setting of the Deer Lake Highlands also may have contained this plant association.

The fourth and final plant association consists of riparian habitats, which are localized and poorly diversified woodlands found in areas of perennial moisture. They include such species as arroyo willow (*Salix lasiolespi*), mule fat (*Baccharis glutinosa*), curly dock (*Rumex crispus*), swamp knotweed (*Polygonum coccineum*), nettle (*Urtica holosericea*), cocklebur (*Xanthium strumarium*) and rabbit foot grass (*Polypogon monspeiensis*). Though this plant association is limited in distribution, it still had significant economic importance in aboriginal times, especially in terms of the acquisition of raw materials for items like baskets, cordage and netting. Riparian habitat would have been present in both of the canyons which border the study area.

The majority of the Chatsworth Ridge Estates study area continues to support native vegetation, with most of the existing disturbance within the study area localized in the Deer Lake Highlands area, proper. Here there are a few cleared and disked areas, an occupied house, and remnants of post-world War II structures, along with a limited network of dirt roads. Again, however, the majority of the study area is relatively undisturbed,

reflecting in part the fact that portions of it are topographically very rugged.

2.0 BACKGROUND STUDIES

2.0 Introduction

In preparation for the Phase I archaeological survey of the study area, a series of background investigations were conducted on the prehistory, ethnography and history of the study area and relevant surrounding regions. We consider below existing knowledge relevant to these topics for the Chatsworth Ridge Estates project area.

2.1 Prehistoric Background

The Chatsworth Ridge Estates project area, lying in western Los Angeles County, is situated in a zone known prehistorically to have comprised a portion of the prehistoric Canaliño culture area (Rogers 1929; Wallace 1955), and historically to have been located just within the territory of the Gabrielino ethnolinguistic group (Kroeber 1925; Johnston 1962; Bean and Smith 1978). Our current understanding of the Canaliño prehistory is summarized below.

Canaliño prehistory was first defined in a chronological system established by D.B. Rogers (1929), working on the Channel Islands and the Santa Barbara coastline. At a later date, Rogers' scheme was modified in terminology and improved with additional and more detailed data and radiocarbon dates by W.J. Wallace (1955), who applied it to southern California more generally. Subsequently, the Rogers/Wallace chronology had been successfully applied to inland Los Angeles County (e.g., McIntyre 1990), and is now recognized as having applicability to a wide area of mesic (i.e., that area west of the xeric desert zone) Los Angeles, Ventura, Riverside, San Bernardino and Orange Counties. Due to the widespread application of this chronological scheme, we employ Wallace's framework for the purposes of this study.

Late Pleistocene Period (Pre-10,000 years B.P.)

Wallace's chronology for southern California includes four time periods,

the earliest of which (Early Man/Big Game Hunting period) was considered speculative, and was correlated with the end of the Pleistocene, or Ice Age. This would represent an occupation prior to about 10,000 years B.P. (Before Present). Although it is likely that inhabitation of the southern California coastal region occurred during this early time period, evidence for such is currently extremely limited. To date, Late Pleistocene archaeological remains in southern California comprise two kinds of evidence. First, in the inland Mojave Desert region, petroglyphs (rock engravings) and surface stone tools have been dated back to approximately 20,000 and 30,000 years B.P., respectively (Whitley and Dorn 1993; Whitley et al 1996). These may well reflect the initial human occupation of North America. The contexts of these dated finds provide only limited kinds of archaeological information and, while there is much more to be discovered about this earliest prehistoric culture, existing data nonetheless suggest that these earliest inland Californians may have dwelled along the shores of Pleistocene lakes; that they exploited chert quarries to make relatively crude stone chopping tools; and that they also made rock art, perhaps as part of shamanistic religious practices.

Second, a limited number of large fluted projectile points have been found in isolated locales in the Mojave Desert and along the California coast. These projectile points functioned as parts of spears and are known to date between 11,200 and 10,000 years B.P., falling within what is called the Paleoindian Period on the Great Plains. On the Plains, such points are associated with the hunting of extinct Pleistocene fauna, such as the Columbian Mammoth. Although it is likely that these spear points were similarly used in southern California, the isolated nature of the discovered artifacts precludes any certain inference about their use or function in the California region.

Uncertainty concerning these early prehistoric cultures results from the characteristic geomorphological instability of the California coastline and the general youthfulness of the southern California interior, combined with the major change in erosional/degradational regimes that occurred at the end of the Pleistocene (Whitley and Dorn 1993). Each of these factors does not favor the preservation of remains from this period. It is therefore likely that Late Pleistocene human occupation of Los Angeles is

under-represented in the local prehistoric record, simply due to problems in site preservation.

Early Millingstone Period (10,000 - 3500 years B.P.)

With the transition towards a modern environment, starting approximately nine to ten thousand years ago, an adaptation referred to as the Early Millingstone Period or Horizon began. This is particularly evident along the coast, where many such sites are found, although a few examples are known from the inland region. Most sites of this stage date between 8500 and 3500 years in age.

Recent studies by Erlandson (1988; see also Erlandson and Colton 1991) provide evidence of a significant, even if small, population of coastal hunter-gatherers in the region before 7000 years ago, or essentially at the beginning of this Early Millingstone period. He has shown that these were neither Big Game hunters, nor specialized, hard-seed gatherers, but instead generalized foragers that relied on a variety of different kinds of terrestrial, coastal and marine resources, and that they were adapted to estuarine embayments that have long-since disappeared from the local environment. Further, his evidence indicates that their primary protein sources were shellfish and other marine resources. Extending a pattern first identified by Meighan (1959) on the Channel Islands, in other words, this suggests that the adaptation to the seashore is a very ancient and long-lived tradition in local prehistory.

In the inland region, perhaps the earliest evidence of the Early Millingstone Period is provided by so-called Los Angeles Woman, a female skeleton found in the La Brea Tar Pits which has been radiocarbon dated to 9000 years B.P. Lacking clearly associated artifacts or other remains, it is difficult to interpret the Los Angeles Woman beyond observing simply that her discovery signals the fact that the inland region was in use shortly after the end of the Late Pleistocene.

Later Early Millingstone sites (post-dating approximately 6000 years B.P.) are dominated by assemblages containing large numbers of groundstone artifacts, along with crude choppers, scraper planes, and other core/cobble tools. These are thought to represent an adaptation to gathered plant foods, especially a reliance on hard-shelled seeds.

Accordingly, it has been common practice to identify any site with a dominance of these plant processing implements as Early Millingstone in age. More recently, it has also been suggested that scraper planes, in particular, may have served in the processing of agave (Kowta 1969; Salls 1985); that the association of groundstone and core/cobble tools represents a generalized plant processing toolkit, rather than one emphasizing hard-seeds, per se (Whitley 1979), and that this toolkit was used in appropriate environmental settings throughout the prehistoric past. That is, that the so-called millingstone toolkit is environmentally rather than chronologically specific and reflects localized exploitative patterns, rather than a chronologically-specific adaptational strategy (Kowta 1969; Leonard 1971; McIntyre 1990). Thus, many inland sites identified as dating to the Early Millingstone Period solely on the basis of their groundstone toolkits may, in fact, not be of such age at all. However, on the coastal strip there continues to be evidence that such sites date to the earlier end of the time-frame. These sites are generally located on terraces and mesas, above the coastal verge, near permanent streams.

Although Early Millingstone period sites are relatively common along the coast, there is little evidence for the occupation of the inland region during this early time period. That is, although the millingstone adaptation to seeds and plants, and toolkits dominated by plant processing tools, are present in the inland zone, they appear to date to a later time period, with true Early Millingstone period occupation apparently restricted to the coastal strip, proper (Whitley and Beaudry 1991; cf. Leonard 1971; McIntyre 1990). Again, it is currently unclear whether this pattern reflects real differences in inland versus coastal settlement distributions, or is simply a function of site preservation problems in the inland region. Whatever the cause, it is worth noting that there are currently very few reliable or plausible chronometric dates from inland sites that are Early Millingstone in age. All current temporal assignments of inland sites to the Early Millingstone period are based on putative diagnostic artifacts but, when these are examined critically, the verity of the early age assignments become dubious. And, too often, such early age assignments are based on functional/adaptive traits rather than stylistic criteria, thus confusing adaptive patterns for temporal ones.

A good example of the confusion of millingstone functional and adaptational patterns for Early Millingstone chronological diagnostics in inland Los Angeles County is provided by the so-called "Topanga Culture", as exemplified by excavations at CA-LAN-1, the "Tank Site" (cf. Heizer and Lemert 1947; Treganza and Malamud 1950; Treganza and Bierman 1958), located in the Santa Monica Mountains immediately south of the San Fernando Valley. This is widely regarded as "Early Millingstone" chronologically, and its base ("Phase I") has been assigned 10,000 years of age, essentially due to the large numbers of millingstones, crude choppers and "cog stones" (see Treganza and Bierman 1958:75, Table 1). But, as Johnson (1966) has rightly pointed out, Phase III of the Topanga Culture is only 3000 years old, as demonstrated by his excavations at CA-LAN-2. That is, it is Intermediate and not Early Millingstone in age. It then must follow that the preceding Phase II can only be considered 3500 to 3000 years old, due to the presence of (Intermediate period) mortars and pestles in the Phase II assemblage. That is, Phase II of the Topanga Culture also can only be Intermediate period in age. Since Phase I lies conformably and immediately below Phase II stratigraphically, it likewise must follow that it immediately predates the Intermediate period Phase II remains. At best, then, Phase I of the Topanga Culture is terminal Early Millingstone or transitional Early Millingstone/Intermediate, but not necessarily of any great antiquity.

This fact is emphasized when it is recognized that one of the key classes of temporal diagnostics said to support the very early age assignment for Phase I at the Topanga Site, the cog stones, were all recovered from the Phase II deposit, even though Treganza and Bierman (1958) incorrectly assign them to the Phase I assemblage (Eberhart 1961:366-7). Thus, there is currently no evidence to suggest any great antiquity for Phase I of the Topanga culture; instead it may simply be 4000, rather than 10,000 years in age, and may represent an early manifestation of the Intermediate Period movement of a millingstone adaptation into the interior, rather than a manifestation of a coastal Early Millingstone culture in the inland zone.

Intermediate Period (3500 - 800 years B.P.)

As implied above, a transitional stage followed the Early Millingstone, which is referred to as the Intermediate Period (Wallace 1955). It is

believed to have begun about 3500 years ago, and to have lasted until about A.D. 1200 (according to the latest revisions; cf. Arnold 1987). It is marked on the coast by a growing exploitation of marine resources, the appearance of the hopper mortar and stone bowl/mortar, and a diversification and an increase in the number of chipped stone tools. Projectile points, in particular, are more common at sites than previously, while artifacts such as fish hooks and bone gorges also appear.

As noted above, cog stones also first appear during the Intermediate Period, although they are widely misinterpreted as Early Millingstone in age. These are relatively small, flat cobbles, about the size of a large biscuit, that were shaped to resemble a kind of mechanical cog or gear. Although the function of these is unknown, it is likely they served as ceremonial objects, and their geographical distribution has an important implication for regional prehistory. As first identified by Eberhart (1961), cog stones are only found from Los Angeles County south and eastward; that is, they are absent in the areas of the Santa Barbara Channel region (Ventura and Santa Barbara Counties) that, historically, were occupied by Chumash-speaking groups. Although speculative, this suggests that the initial distinction between the Hokan Chumash and Tadic-speaking groups (which included the Gabrielino) may have developed as early as 3500 years ago (cf. Kowta 1968:50; McIntyre 1990:5), rather than only 1500 years B.P., as Kroeber (1925) first hypothesized. That is, the distribution of these "ceremonial" artifacts essentially follows the boundaries of ethnolinguistic groups during the historical period, suggesting that such boundaries may have been more-or-less stable for about 3500 years. Notably, this hypothesis is supported by excavations at Intermediate Period site CA-LAN-2233, in the Santa Clara River Valley to the north. At this site, osteometric and DNA analyses indicate that the resident population was non-Chumash genetically (Waugh 1999).

As also implied above, there is growing evidence that it was at the beginning of this Intermediate Period that inland sites, such as those found in the Conejo area on the north side of the Santa Monica Mountains, the upper Santa Clarita Valley, the Antelope Valley, and western Riverside and San Bernardino Counties, were first established and occupied. Whether this pattern holds for the interior Los Angeles Basin has yet to be determined, but it seems likely. This suggests the

exploitation of more varied environments and perhaps an increase in population at this time and, again, it may correlate with Kroeber's "Shoshonean Wedge" moving into mesic southern California at circa 3500 years B.P. (Whitley et al n.d.; cf. Whitley and Beaudry 1991). In general, however, the Intermediate Period can be argued to have set the stage for the accelerated changes that took place immediately following it.

Canaliño/Late Prehistoric (800 to 200 years B.P.)

With the transition to the Canaliño or Late Prehistoric period at A.D. 1200, we can correlate local prehistory with the ethnographic societies as described (even if in abbreviated form) by early chroniclers and missionaries. However, this is not to suggest that local societies and cultures were in any way static, for the transition to the Canaliño period was marked by the evolution and eventual dominance of a sophisticated maritime economy. Further, among the Chumash to the west, a rise in social complexity has been shown to have been associated with the development of craft specialization, involving the use of standardized micro-drills to mass produce shell beads on Santa Cruz Island (Arnold 1987), which occurred during this period. This, apparently, contributed if not caused the appearance of a simple chiefdom in the southern Chumash region (cf. Whitley and Clewlow 1979; Whitley and Beaudry 1991).

Although we do not have evidence that the Gabrielino developed into a chiefdom like the neighboring Chumash, the Canaliño period nonetheless witnessed a florescence of local aboriginal culture paralleling the Chumash case. This included a substantial growth in population, the establishment of permanent settlements on the coast (and probably at favored locales in the inland area), a high degree of sociopolitical complexity, and the development of a very sophisticated maritime economy. It was during the Canaliño period, thus, that the occupants of the Santa Barbara Channel and Los Angeles County region achieved levels of cultural and social sophistication perhaps unrivaled by hunter-gatherer-fisher groups anywhere else in the world (Wallace 1955; Johnston 1962; Landberg 1965; Brown 1967).

2.2 Ethnographic Background

As noted above, the study area falls within the ethnographic territory of the Takic-speaking Gabrielino; specifically, of the Fernandeño dialect of Gabrielino. "Fernandeño" and "Gabrielino" are terms of Spanish derivation, resulting from the standard missionary practice of naming indigenous peoples after the mission to which they were attached, in this case the Missions San Fernando Rey and San Gabriel Arcangel, respectively. True indigenous names for the Gabrielino included *Kij* or *Kizh* (Johnston 1962; Reid 1968), the etymology of which is unknown; *Kumivit*, "easterner"; and *Tobikhar*, etymology, again, unknown (Bean and Smith 1978:548), although it is not clear that any of these terms were actually employed by the Gabrielino as self-referents (see below). In contrast, the Fernandeño were known to the Gabrielino as *Pasekwarum*, from *Pasekngna* (referring to a village near the San Fernando Mission). Thus, although "Gabrielino" and "Fernandeño" are in some senses inappropriate, they continue in standard usage.

Regardless of appellation, what historically have been referred to as the Gabrielino extended from Orange County north through the Los Angeles Basin to the crest of the San Gabriel Mountains, including the headwaters and watershed of the San Gabriel River, and from the coast eastward to include Mt. San Antonio (Mt. Baldy) and western Riverside and San Bernardino Counties. To the west, Gabrielino territory extended to Topanga Canyon, and included the San Fernando Valley (Kroeber 1925:Plate 57; Johnston 1962; Bean and Smith 1978a:538). Fernandeño was spoken primarily if not exclusively within the confines of this large inland valley.

According to Bean and Smith (1978a:538), the Gabrielino were culturally extinct by the beginning of this century -- that is, prior to the recording of any detailed ethnography on them -- various sources, and analogies with better known surrounding groups, can be employed to reconstruct aspects of their ethnographic lifeways. For example, the Gabrielino and the linguistically-related Serrano shared many, if not most, cultural traits (Kroeber 1925:578-580; Bean 1972:69, 1978:575-576). We base the following reconstruction, accordingly, on Gabrielino, Serrano and Cahuilla sources (e.g., for the Gabrielino, see Dakin 1939, Reid 1968, Kroeber

1925, Johnston 1962, and Bean and Smith 1978a; for the Serrano, see Benedict 1924, Kroeber 1925, Strong 1929, and Bean and Smith 1978b; for the Cahuilla, see Barrows 1900, Kroeber 1908, 1925, Hooper 1920, Strong 1929, Bean 1972, 1978; and Bean and Saubel 1972, etc.).

The terms "Gabrielino" and "Fernandeño" strictly apply to groups of people united only by the use of a dialectical variant of the Gabrielino language (itself a Cupan language of the Takic branch of the Uto-Aztecan linguistic family). That is, they imply no necessary sociopolitical unity (as in a single 'tribe') and, in fact, a series of different political units may have existed among the Gabrielino at the time of Spanish contact, explaining why there were no generic terms for these groups as unified corporate units. Further, there may have been as many as six dialectical variants of the larger Gabrielino language (Kroeber 1925:620), the best known of which was Fernandeño (cf. Englehardt 1927).

Based on these ethnographic sources combined with early Spanish accounts, we may confidently infer that the inhabitants of the San Fernando Valley region were hunters-gatherers, with subsistence emphasizing acorns, yucca, juniper berries, sage seeds, mesquite, pinyon and islay and other plant resources. Following a sexual division of labor common throughout native California, women were principally responsible for the acquisition and preparation of plant foods. Game was also hunted, with small animals, such as rabbits/hares and rodents, probably representing more significant contributions of meat protein than larger game, such as deer. Women and children contributed to the hunting (often with nets and drives) of the smaller game. The large game, however, was the exclusive domain of the adult male hunters. Also following practices common throughout the state, specific resources exploited at any given time were a function of what was then seasonally available. Since this was somewhat a function of time of year and elevation, a pattern of transhumance was followed, indicating that only a few of the local villages (exclusive of those on the coast) would have been inhabited year around. Instead, inhabitation followed a pattern of population aggregation into large villages, usually during the Fall/Winter, when stored resources like acorns and pinyon nuts were eaten, and dispersal into single family units, typically during the Spring/Summer, when resources were more widely distributed.

It is likely that Gabrielino inhabitants wintered in large villages near permanent water sources on the Los Angeles Basin floor, whereas the Fernandoño would have occupied similar villages at springs on the San Fernando Valley floor or foothill edges. Upland zones, such as are found in the San Gabriel and Santa Susana Mountains to the north and the Santa Monicas to the south, would have been exploited seasonally, during the Spring, Summer and Fall, when valuable plant species ripened (e.g., on the northern slopes, pinyon nuts in the fall). Small, single family camp-sites would have been established near to the plant resources at this time. The highest elevations of the mountains, comprising pine forests, would probably only have been usable for hunting, with only minimal camp-sites established.

Social and political organization can be assumed to have been similar to the well-described systems of the Cahuilla (see Strong 1929; Bean 1972, 1978). These involved patrilineal moieties and clans of three to ten lineages that served as political-ritual-corporate units (Bean 1978:580). Each lineage maintained a village site and resource exploitation area. The office of the ceremonial leader was usually restricted to the founding lineage of the clan, which also owned the ceremonial house and ceremonial bundle. Each lineage had its own lineage leader who served in a variety of sacred and secular capacities, and who met with other such leaders to adjudicate inter-lineage disputes. This office was hereditary and patrilineal. He was assisted in many tasks and responsibilities by a paxa, or assistant, also an inherited office. Ceremonial song-leaders also aided in ritual activities (ibid).

It is also likely that religion followed the patterns found among surrounding groups. In this case, shamanism would have functioned as the central element. This posits a direct and personal relationship between each individual and the supernatural world, with this relationship enacted by entering a trance or hallucinatory state (usually based on the ingestion of psychotropic plants, such as jimsonweed and, especially, native tobacco). Shamans, per se, were considered individuals with an unusual degree of supernatural power, and served as healers or curers, diviners, and controllers of natural phenomena (such as rain or thunder). Shamans are also known to have produced the rock art of this region,

which depicted the hallucinations and spirits they observed in their vision quests. In addition, however, rock art was also painted by male and female initiates at the conclusion of a puberty ritual. Importantly, this initiatory art was also intended to display the spirit helper the initiate received during these ceremonies. Thus, two kinds of ethnographic rock art can be expected in the region: sites owned and made by shamans, and sites used for village initiations (Whitley 1992, 2000).

Given the early disruption of aboriginal lifeways in historical times, it is not surprising that little in the way of information about historical villages and aboriginal place names has been recorded for Gabrielino and Fernandean territory. However, the exploration and settlement of the San Fernando Valley region did result in the recording of a small number of place-names. As noted above, *Pasekngna* was a village near the San Fernando Mission, while *Achoicomngna* was the location of the mission itself. *Tuhungna* was a village located on the north bank of Big Tujunga wash, while *Muhungna* served the same purpose near the mouth of the Little Tujunga. *Tongva* was another village name in the Tujunga area, and was sometimes used to refer to the residents of this area, while *Kawengna* contributed its name to the Cahuenga Pass.

2.3 Historical Background

Local history may be best considered with reference to three periods: Spanish, Mexican, and American. These are discussed below in turn.

The Spanish Period (A.D. 1542 - 1821)

Initial contact between the indigenous Gabrielino and the Spanish occurred in October, 1542, with the arrival of Juan Rodriguez Cabrillo along the Los Angeles County coast. This was followed in 1602 by the Vizcaino expedition, which landed on Catalina Island and visited local inhabitants there (Bancroft 1963). As exploratory expeditions, the early Spanish sailors' impact on the Gabrielino is difficult to gauge: while they clearly resulted in no permanent European settlements and made no consequential forays into the interior, it is nonetheless possible that they may have introduced diseases with widespread deleterious effects on the local population.

Substantial contact between inland Gabrielino and the Spanish did not occur for over two-hundred years after Rodriguez Cabrillo's initial foray. This event was the arrival of the overland party of Don Gaspar de Portolá in the Los Angeles Basin in 1769, preparatory to the establishment of a Spanish colony in the region (Brandes 1970; Bolton 1971; Boneau Companys 1983). Subsequent to a stop at what would become the pueblo of Los Angeles, Portolá and his men passed through the San Fernando Valley before preceding northwards to the Santa Clara River Valley and then turning west to the sea. Called the "Encino Valley" when the expedition visited it on August 5 and 6, 1769, the San Fernando Valley was christened *Santa Catalina de Bononia de los Encinos* by Father Crespi, chaplain of the expedition.

Following Portolá's expedition, Spanish settlement of Upper California was initiated with the establishment of a series of missions, presidios (forts), and pueblos (towns). Mission San Gabriel Arcangel, in 1771, was the fourth mission founded in Upper California, and represented the first Spanish settlement in the greater Los Angeles area. With the appointment of a military governor, Felipe de Neve, in 1775, Spanish efforts to establish civilian settlements independent of the missions were also initiated. De Neve selected a possible site for such a pueblo on the Porciuncula (later Los Angeles) River in 1777 and began the process of enlisting settlers to inhabit it. These were derived from colonies in Sinaloa and Sonora and included settlers of Native American, African and Spanish descent, as well as various admixtures thereof. In all, 11 families comprising 44 individuals settled the newly founded pueblo, arriving between June and October, 1781. *Nuestra Señora de la Reina de los Angeles de Porciuncula*, as the new town was called, was officially chartered on September 4, 1781, shortly before all of the settlers had arrived (Bancroft 1963; Robinson 1981). This was the origin of what would become the City of Los Angeles.

The growth of the pueblo was relatively rapid, with population more than tripling to 139 by 1790 - that is, in less than ten years - with 29 adobe residences constructed, a town hall, barracks, bodega (municipal storehouse), and a surrounding adobe wall. This growth was aided by the establishment of ranchos, or large ranch concessions, the first three of

which were granted in Los Angeles County in 1784.

Settlement and use of the San Fernando Valley, somewhat isolated from the growing pueblo by the Hollywood Hills (the eastern extension of the Santa Monica Mountains), however, lagged behind the growth of the pueblo itself and the Los Angeles Basin to the south. The initial Euro-American entrants into the valley were apparently illegal users of the lands, the rights to which were retained under Spanish law by their Native American occupants unless and until they were formally awarded by the government to non-Indian recipients. Records on these early Euro-American squatters are close to non-existent, as might be expected. One who has entered the record and who figures directly in the history of the valley, however, is Francisco Reyes. Reyes arrived in California from Mexico in 1787, built an adobe in the pueblo of Los Angeles, and was alcalde (mayor) there between 1793 and 1795. He also built a house on an illegal ranch he was operating in the San Fernando Valley at this same time. He and one Comelio Avila kept their livestock at this ranch, which shortly thereafter became the foundation for the Mission San Fernando (Engelhardt 1927:140-141; 1930:509-513). The early Euro-American history of the San Fernando Valley is necessarily tied to the development and decline of this mission, even though it does not fall within the current study area, per se.

The decision to build a mission in the San Fernando Valley was reached in 1797, when ecclesiastical authorities recognized a need for a mission intermediate between San Gabriel and San Buenaventura (Ventura). An expedition was sent out at that time to locate a favorable spot for such an establishment. After scouting locales in the Simi, Santa Clara and Conejo Valleys, Reyes' Ranch with its nearby Fernandefio village of *Achois Comihabit* (rightly, probably "*Comihangna*") was visited and chosen as the preferred spot. Father Vicente de Santa Maria, chaplain to this expedition, noted that: "To this village belong, and they acknowledge it, the gentiles of other rancherias, such as *Taapa*, *Tacuyama*, *Tucuenga*, *Juyunga*, *Mapipinga*, and others, who have not affiliated with Mission San Gabriel" (quoted in Engelhardt 1927:5). Even at this early date, then, it appears that Native American settlement had been disrupted, and inhabitants of distant villages were congregating in newly formed aggregations. This set the stage for population distribution during the

mission period in the valley, per se: the further aggregation of Fernandefio, Tataviam and some Chumash peoples into a single settlement, based on a corporate system of agricultural production.

The dedication and then construction of the mission followed closely thereafter. On September 8, 1797, Father Fermin Lasuen dedicated the mission and baptized ten children (Engelhardt 1930:513). It was named San Fernando Rey in honor of King Ferdinand V, at the request of the Spanish king, Charles IV (Thompson and West 1880:104). Father Francisco Dumetz (1743 - 1811) served as first pastor at San Fernando.

Dumetz had been born in Majorca, Spain, and first arrived in California in 1771, bringing with him the first sheep introduced into Upper California. He presided over nearby Mission San Buenaventura from 1782 to 1797 before being put in charge of San Fernando. At San Fernando he was responsible for erecting the initial buildings, building the second church and quadrangle and the so-called Christian village, and for starting the third and final church, begun in 1804. He was reassigned to Mission San Gabriel in 1805, where he died in 1811 (Geiger 1969:66-69).

Dumetz established a stable institution which expanded in size and influence over the next few years. This included the development of the Asistencia (or sub-mission) of San Francisco Xavier, in the Santa Clara Valley, in 1804. This served both ecclesiastical and economic needs, as it provided a religious center for Native Americans living in the Newhall area, as well as access to additional grazing and farming lands for the growing mission population. Growth and stability of the mission was not, however, continuous during the Spanish period. In 1810 Mexico declared independence from Spain. This was not gained for another eleven years but, during this decade, economic conditions deteriorated radically. Soldiers and priests, for example, were essentially not paid, and the missions were forced to contribute to the upkeep of the local Mexican government (Englehardt 1927:35). Because of this disruption the mission system to begin to fray, although circumstances deteriorated much more rapidly once independence was achieved.

The Mexican Period (A.D. 1821 - 1848)

With Augustin de Iturbide's *Plan de Iguala*, proclaimed on September

16, 1821, Mexico finally achieved independence from Spain. Shortly prior to independence, however, a new pastor was assigned to Mission San Fernando, Father Francisco Gonzalez de Ibarra. Gonzalez de Ibarra had the unfortunate luck to run the mission during its greatest and most devastating period of decay: 1821 to 1835.

Gonzalez de Ibarra (1782 - 1841) was born in Navarre, Spain, arriving in America in 1819. He was first assigned to Monterey in 1820 and was transferred to San Fernando in 1821. Prior to his arrival, Mission San Fernando had been responsible for 2442 baptisms from the period of 1797 to 1820, averaging over 105 per year. During Gonzalez de Ibarra's 14 year tenure baptisms totaled only 412, dropping to an average of less than 30 per year. Similarly, the mission's herds of cattle dropped from a high of about 12,000 to approximately 7,000; while sheep were reduced from 7,600 to around 4,000 (Geiger 1969:110-111). These conditions resulted from the increasing financial demands made by the civil government on the missions and the resulting stress this placed on the indigenous population. Shortly after Mission San Fernando was secularized by the government in 1834, Gonzalez de Ibarra was so dispirited by these conditions that he fled California for Sonora, abandoning his ecclesiastical post without permission from his superiors. Although this act was sufficiently grievous to warrant de-frocking, his superiors recognized the very unusual circumstances which precipitated it and, following the reversal of secularization, allowed him to return to California where he eventually died, in good graces, at Mission San Luis Rey (ibid).

Gonzalez de Ibarra was, however, a good administrator regardless of the difficult circumstances under which he was given his charge. The result was that even in its decline Mission San Fernando was one of the healthier of the California missions, and so was coveted by civil authorities as the mission system waned. The first formal step in this process (aside from the increasing demands to provide financial support to the civil government and military) was an 1827 decree requiring the missions to define their lands and assets. The San Fernando Mission declaration listed its domain as stretching 10 leagues from Cahuenga to Triunfo and northwards for five leagues to Camulos on the west and San Francisco Xavier on the east. It also declared that it was raising wheat, corn and

beans and had about 6,000 cattle and 8,000 sheep at that date (Englehardt 1927:47).

The next formal action in the disbanding of the missions occurred in January, 1833, when Governor Jose Figueroa signed an act "secularizing", which is to say confiscating, the missions. Lt. Antonio del Valle was commissioned in 1834 to secularize San Fernando and, in 1835, was assigned to serve as mayordomo or administrator over its operations (ibid:50). He inventoried the mission holdings, recording that they included \$5,700 in various assets, 32,000 grapevines and 1600 fruit trees, with a native population of 541. Del Valle also recorded that considerable difficulty was occurring with this native population, who according to him were responsible for constant thefts of horse and cattle (ibid:50-51). The Native American population had apparently recognized by this time that their best recourse was to retreat to more remote spots, taking with them some of the livestock and produce which they had spent their lives raising and growing. Still, some of them stayed on as the mission was reduced to the status of a parish. In 1839, when the Asistencia de San Francisco Xavier was removed from the mission and awarded as a rancho to del Valle, San Fernando still retained 416 Indian inhabitants, all of whom presumably worked as agricultural laborers for the new secular administrators (ibid:59).

Further dissolution of the mission system occurred in 1845 when Governor Pio Pico proclaimed that mission lands would either be sold by the civil government, or leased to individuals for commercial use. Pico's brother Andres and Juan Manso were awarded a nine year lease for San Fernando, at a term of \$1,100/year, in 1846 (ibid:64-65). However, the ensuing war with the United States put a financial strain on the government, requiring Pico to sell the leased San Fernando mission lands to Eulogio de Celis for \$14,000, with the nine year term of Andres Pico and Manso still intact (Robinson 1961:12). Total land included in this sale was 13 square leagues, exceeding any previous land transfer in California because this sale was not constrained by the size restrictions placed on the award of rancho grants.

The American Period (A.D. 1846 -)

The American Period brought great changes to the San Fernando

Valley but, unlike other regions within suburban southern California, this did not involve a continuous and relatively quick evolution from a large mission tract to the modern suburbanized and urbanized valley which exists today. For the southern half of the valley, in particular, the history of change in land-use comprised an initial phase of large-scale agricultural use (1846 - 1888) followed by a period of subdivision into small farms and ranches (1888 - 1940), followed ultimately by the suburban development evident today (1940 - present). The northern and especially northwestern areas, including the study area *per se*, were developed much later. These phases may be considered in turn.

With the transition to U.S. control of California an initial governmental concern was the examination and, where appropriate, validation of preexisting rights to land ownership. A Lands Commission was appointed in 1851 to hear lawsuits concerning contested lands. Among the first of those heard involved the mission lands, resulting from an action instituted by Bishop Jose Alemany in 1853. The civil possession of Mission San Fernando was determined illegal by the commission, and the mission buildings and lands immediately surrounding them (about 170 acres) were patented back to the Catholic Church in 1862. By this point, however, the mission was essentially in ruin.

The remaining Ex-Mission San Fernando lands stayed in civil hands, specifically under de Celis' ownership, albeit he (or, more rightly, his heirs) did not receive clear title in the form of a US patent until 1873. Moreover, he sold an undivided half interest to Andres Pico in 1854 for \$15,000. Pico continued to use the land for cattle ranching, as he had under the terms of his former lease with the Mexican government. Pico subsequently sold his holdings to his brother Pio in 1862. Pio Pico, like many other Californians, suffered greatly from the droughts of the 1860s, causing him to mortgage his property to a New York bank. In 1869 he sold these mortgaged lands to the San Fernando Farm Homestead Association for \$115,000 (Dumke 1944:98-99; Jorgensen 1982:85). This group got the Ex-Mission lands partitioned from de Celis' heirs, taking as their share about 60,000 acres which constituted the southern half of the valley (Robinson 1961:21). This represented an investment of less than \$2/acre for the area that would one-day become North Hollywood, Van Nuys, Reseda and Canoga Park.

The financier behind the San Fernando Farm Homestead Association was Isaac Lankershim, a Bavarian who had become rich as a grain farmer in northern California. Lankershim hired Isaac Newton Van Nuys to manage his newly acquired holdings, which they quickly put into livestock and then wheat production. Their first two years of farming were unsuccessful, largely because they had no ready means to ship their grain to port. The Southern Pacific Railroad, however, began the north-south rail route from Los Angeles to San Francisco in 1873 by laying 25 miles of track north out of Los Angeles. This first stretch of tracks (running through the area of modern Burbank) terminated at a townsite in the northern half of valley which was named San Fernando, after the mission. SPRR also extended a line from Los Angeles south to the port at Wilmington (Nadeau 1965:81-82). The establishment of the northern rail line directly led to the beginnings of development in the San Fernando Valley, albeit initially this was restricted to the northern half, some distance away from the East-West Transportation area study area.

The San Fernando line, still, provided the means for making Lankershim's large scale wheat farming economically successful. Initially, however, he and Van Nuys had to go to the effort and expense of constructing a wagon road across the Sepulveda Pass as a leverage to get the SPRR to give them a reasonable freight rate from their valley sidings to the wharves at Wilmington. Once these arrangements were worked out, truly massive farming began, with 10,000 acres seeded in wheat in 1875 (Nadeau 1965:89).

Lankershim's San Fernando Farm Homestead Association was succeeded by the Los Angeles Farming and Milling Company in 1880 in what looks largely like a paper transfer, name change, and minor reshuffling of investors; common usage still termed the property the "Lankershim Ranch" into the early 1900s (e.g., *Los Angeles Daily Times*, September 24, 1909, page 1). Large-scale farming, intended for the world market, continued into the late 1880s, when the world wheat supply exceeded demand and the price per bushel began to decline steadily (Jorgensen 1982:82). This led to the second phase of the American land-use history of the valley: a shift from large scale agriculture towards sub-division and the development of small-holdings.

This process began in 1888 when Lankershim divided off and bought outright for himself 12,000 acres of the Los Angeles Farming and Milling Company holdings in the east end of the valley (extending west to about Whitsett Avenue). With this he created the Lankershim Ranch, Land and Water Company (Dumke 1944:99). With his son J.B. he subdivided this into small ranches and farms, selling them for \$5 to \$55 per acre. The population center for this development was a townsite located along the road running from Cahuenga Pass to San Fernando (near the corner of what is now Lankershim and Tujunga Blvds.), which they named Toluca. Subsequently the name of this town was changed to Lankershim and finally North Hollywood, when the local merchants decided there was something to gain by hitching their name-recognition to the developing allure of Hollywood. Toluca failed to grow into a large settlement during this early period, although a hotel, school, some stores and several houses were built at this locale shortly after it went on sale (ibid). Still, Lankershim realized \$200,000 in land sales in 1888, and the value of his land apparently went up rapidly. A front-page advertisement in The Times of April 7, 1889, for example, states the following:

LANKERSHIM RANCH LAND AND WATER COMPANY - 12,000 Acres: Finest San Fernando Valley Lands, 10 Miles Northwest of Los Angeles on Main Line of the Southern Pacific Railroad, Now Offered in Tracts of 5, 10, 20 and 40 acres, \$35 to \$165 per acre! Terms, One-quarter cash. Balance 1, 2 and 3 years. Deferred payments bear interest at 7 per cent per annum.

Similar subdivisions were established in other parts of the valley, notably, the northern half, but one factor greatly impeded the development of small farms: an absence of water.

Due to complicated water rights, ultimately tied to the founding of the pueblo of Los Angeles under Spanish law, an 1881 California Supreme Court Decision held that all of the water in the San Fernando Valley belonged to the City of Los Angeles. Valley residents were therefore denied access to the surface water in the Los Angeles River, and they were denied the right to drill wells. Confounding matters even more, because these farms were situated outside of then-existing City of Los Angeles

limits, the city could not legally sell water rights to them. Although Los Angeles was relatively slow to enforce its rights, between 1900 and 1905 it instigated proceedings against 200 valley farmers and ranchers (Jorgensen 1982:140-141). This circumstance had a very simple effect: it further delayed the development of the San Fernando Valley relative to surrounding regions of southern California, such as the nearby San Gabriel Valley, until water became available. This effectively occurred in 1913, when the Owens Valley Aqueduct was completed, making water for the general Los Angeles region plentiful. In order to gain access to this water the inhabitants of the San Fernando Valley annexed themselves to the City of Los Angeles shortly thereafter. Note, however, that the Chatsworth Ridge Estates study area lies a short distance west of the limits of incorporated Los Angeles, signaling the fact that it was peripheral to these early historical developments.

As is usually the case, a small group of leading citizens recognized, in advance, the economic potential of the valley once water became widely available, and so laid plans for its development. A syndicate of 30 men, including notable figures such as Harry Chandler and Harrison Gray Otis, founded the Los Angeles Suburban Homes Company by purchasing the 47,500 acres Lankershim Ranch from the Los Angeles Farming and Milling Company in 1909. (This was effectively all the land the company retained after divesting 12,000 acres to Lankershim for his Lankershim Ranch, Land and Water Company development). Their price was \$2.5 million. They were led by H.J. Whitley, known as the "father of Hollywood", who served as general manager for the syndicate (*Los Angeles Daily Times*, September 24, 1909, page 1; Robinson 1961:37).

Whitley was responsible for the development of Hollywood in 1903, but even earlier had come to Los Angeles with a history of successful land development. Born in Canada, he started his American career as a professional townsite developer for the Rock Island and Northern Pacific Railroad, and later created a series of successful banks in Oklahoma prior to his arrival in California (Jorgensen 1982:144). His involvement with (and the activities of) the other members of the Los Angeles Suburban Homes Company extended beyond the San Fernando Valley, however: shortly after starting the development of the valley they purchased the 270,000 acres Tejon Ranch from Truxtun Beale (son of General Edward F.

Beale) for \$3 million, and were involved in a series of similar purchases at Dana Point, and in New Mexico and Baja California (Crowe 1957:118). Whitley's recognition of the development potential of the San Fernando Valley, however, apparently foreshadowed even that of his fellow syndicate members. While developing Hollywood he had the foresight to recognize the importance of Cahuenga Pass as the primary access into the valley. As a result, Whitley purchased title to the Cahuenga Pass years before the syndicate was established, thereby controlling commercial development in the "gateway to the valley".

The boundaries of the syndicate's valley purchase started at the western side of the Rancho Ex-Mission lands (i.e., Encino) and ran eastward to Lankershim's development (at Whitsett Ave.); north to Roscoe Blvd; and south to the crest of the Santa Monica Mountains. According to a period account, the property was 15 miles long and 6.5 wide (*Los Angeles Daily Times*, September 24, 1909, page 1). The map for this subdivision was filed on March 14, 1911, and it was designated "Tract 1000", the largest subdivision in Los Angeles County history. The principles in the syndicate reserved certain portions of the tract for their personal development and/or use, with their personal parcels ranging up to 1000 acres in size. Whitley and Chandler both took only 500 acres each, located near the corner of modern Van Nuys Blvd. and Sherman Way. Whitley built his own mansion on this land, a three-story Italianate home, which faced modern Van Nuys Blvd. and was located just south of the town center of Van Nuys. In later years it served as the Praisewater Funeral Home (Jorgensen 1982:150).

Three townsites were laid-out by Whitley: Van Nuys; Marian (now Reseda); and Owensmouth (Chatsworth), due south of the study area. Critical to the development of these, beyond water, was transportation or, more precisely, accessibility. This appeared in a series of forms. First, the SPRR constructed an east - west rail line across the valley in the late 1890s. Known as the Chatsworth Park Branch, it was part of the effort to create a coastal route through Simi Valley, Ventura and ultimately Santa Barbara before heading north (cf. Cameron 1963). One outcome of this line is that it made the townsite of Owensmouth, in the northwest corner of the valley, easily reached, but it also opened-up all of Whitley's development area. The Chatsworth Park Branch followed a route west from Lankershim

essentially along what is now Chandler Blvd., heading northwest in the vicinity of Coldwater Canyon to skirt the modern location of L.A. Valley College, and then due west following a route that runs parallel to and a short distance north of modern Oxnard Blvd. This is one of the alternative routes for the current proposed project, and still constitutes a rail right-of-way.

The second improvement in transportation was the construction of an all-weather east - west roadway, making the valley accessible to cars, horses and wagons and, ultimately, the electric trolley. Whitley was responsible for the construction of such a thoroughfare, then known as Sherman Way, which comprised the first real road in the valley beyond the existing north - south route (Lankershim Blvd.) which ran from Cahuenga Pass to San Fernando. Sherman Way was constructed in 1911 (Jorgensen 1982:122).

A period account, published in *Sunset Magazine* in 1914, describes Whitley's Sherman Way in glowing (if not florid) terms, pointing to the fact that it represented a state-of-the-art transportation area and required an almost unheard of investment for that time. As this early author notes:

[Whitley] made it two hundred feet wide, with the trolley in the center and a drive way on either side. He laid an oil macadam pavement for general traffic and an asphalt concrete pavement for exclusive automobile traffic, built concrete curbs for sixteen miles of the twenty-two...He laid out a strip of parking along the trolley tracks, other fifty-foot strips of parking on either side. Then he proceeded to embellish the highway. First he planted rosebushes five feet apart, four rows of them on the main boulevard, two rows on the connecting links, fifty miles of roses in all. Not the ordinary hedge variety but blooded stock...Behind the roses he planted rows of exotic shrubs, oleanders red and white...Behind the bushes he set out rows of magnolias from the south, of flowering acacias from Australia, alternating with stately fan-palms from the Canaries. Next he jumped to India, to the shoulders of the Himalayas, planting a double row of the deodars made famous by Rudyard Kipling. Behind the silvery gray foliage of the deodars he found room for more ornamental shrubs, and at the outer edges of the broad parkings he provided somber

Monterey pines as a fitting background. Then he rested.

If there is, anywhere, a highway that exceeds Whitley's twenty-two mile boulevard in width, length and in variety and character of its arboreal ornamentation, it has succeeded effectively in hiding its light under a bushel basket.

(Woehlke 1982 [1914]:125)

Further enhancing the effect of this broad highway, Whitley lighted its entire length with "ornamental electroliers", putatively costing \$100,000 alone to install. Having established such a standard of elegance for the boulevard, no "pioneer shacks" were allowed to be built anywhere in its vicinity (*ibid*). And with the initiation of the Pacific Electric Company's "red car" service, running 16 trains a day from Van Nuys to Hill St. down the middle of Sherman Way, the San Fernando Valley was finally opened for residential development.

The route of this twenty-two mile grand boulevard ran from Lankershim west along what is now known as Chandler Blvd. to Van Nuys Blvd. There it headed north to modern Sherman Way, where it again proceeded west, thereby connecting the townsites of Van Nuys, Reseda and Chatsworth with Lankershim. The original design of this roadway is still evident in the divided roadbed found in Chandler and Van Nuys Blvds. and Sherman Way, as well as the retained name of Sherman Way itself. The eastern segment of one alternative route for the current project follows the route of Whitley's boulevard from Lankershim west along Chandler approximately to Coldwater Canyon.

The combination of available water and accessibility finally even if belatedly opened up the San Fernando Valley for occupation. According to the 1910 census the valley had only about 3300 occupants; 65% of these were living in the older and more established town of San Fernando; about 26% resided in Lankershim; and the remaining 9% were residents of Chatsworth. But by 1940 population had exceeded 200,000 (Jorgensen 1982:90, 153), resulting in an average growth rate of almost 7,000 new inhabitants per year during this 30 year period. Much of this growth was precisely in those portions of the valley developed by Whitley.

Van Nuys was the focus of this initial spurt of growth, as it was the first

project initiated by the syndicate. Town lots in Van Nuys were put on the market in 1911, while the open areas between this townsite and Reseda and Chatsworth were sold as small ranches and farms. These, in fact, were the primary emphasis of the development, which was marketed as a rare opportunity to obtain farming land within close proximity to Los Angeles. A period account (*Los Angeles Daily Times*, September 24, 1909, page 1) reporting the initial sale of the Lankershim Ranch to the syndicate, for example, made the following announcement:

CHANCE FOR SMALL RANCHERS

In the last two or three years lands of similar nature in this section of the State have been bringing prices so high as to oblige persons seeking acreage to go up into the fertile San Joaquin or Imperials Valleys...Within a very short time, according to the plans of the new developers, opportunity will be afforded for thousands to obtain at a fair price such lands as they desire, close to Los Angeles - so close that a trolley car could take the run in from thirty-five to forty minutes, the time dependent on the portion of the big tract set upon...The soil is uniformly rich and deep and of an alluvial character. It is declared to be of the best in Southern California for alfalfa, small fruits, and diversified farming. It is the largest single body of fertile, level land in this part of the State, and said to be the largest single body of land lying so near a big city, in the United States.

Chicken ranches were particularly common during this period, with the valley referred to as the "Petaluma of the South", in reference to this northern California town's large poultry industry (Jorgensen 1982:151).

The valley retained its primarily rural flavor through the Depression, serving as a region of small farms and fruit orchards (Robinson 1961:41). The Depression and subsequently World War II then further delayed the development of the valley. It was not until after the war that the San Fernando Valley was fully transformed into the large area of suburbs that it is today.

Although the early creation of Van Nuys, Reseda and Chatsworth resulted in a series of nodes of early development that were dispersed across the

valley, in some respects the overall development of the valley still followed a south to north and east to west trajectory, with the northern and western sides being the last to fully suburbanize. The southern foothills of the Santa Susana Mountains, which include the Chatsworth Ridge Estates study area, is a good example of this fact with this current project area still undeveloped. Because of its location away from the open flats of the valley where all early development occurred, it thus fell outside of the area of historical development and significant use.

3.0 ARCHIVAL RECORDS SEARCH

An archival records search of archaeological site maps, records and files was conducted at the UCLA Institute of Archaeology, Archaeological Information Center (AIC) by the AIC staff. This was intended to determine whether the Chatsworth Ridge Estates study area had been previously surveyed by archaeologists, and/or whether archaeological sites had been recorded on it. The complete results of this archival records search are included here as Appendix A.

Site files at the AIC indicate that twelve previous investigations had been conducted within or adjacent to the study area although the study area in its entirety had never been systematically surveyed. The two most pertinent of these previous studies were conducted in 1990 and covered a total of 99 acres in the southeastern and south-central portions of the property.

As a result of these and other studies, four prehistoric and three historical (Euro-American) archaeological sites had been recorded within the study area; an additional prehistoric site is located off-property but is believed to potentially extend into the study area (see Figure 2). These previously recorded sites, and the work that has been conducted on them (Bissell and Becker 1990), are as follows:

- 1) CA-LAN-209 was first recorded in 1978 by R. L. Pence and was subsequently rerecorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. At that time, the site was estimated to be approximately 400 by 300 meters in size, and was described as a large habitation locale (camp) with midden soils, three rock shelters and cupule petroglyphs on one large sandstone outcrop.

This site was originally recorded to the south of the study area. During the 1990 rerecording, however, the northern edge of CA-LAN-209 was argued to extend onto the southern end of the study area; specifically involving the three rockshelters and cupule-covered outcrop, which were recorded as part of the site area. It

was also noted that a large portion of the site had apparently been destroyed by the construction of Highway 118. Hence, only a portion of the site still exists, and a part of this may fall within the study area.

2) CA-LAN-649 was rerecorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site measures approximately 240 by 80 meters and is a large stone tool quarry/workshop that contains numerous quartzite cores, flakes, hammerstones and scrapers. As recorded, the southwestern margin of CA-LAN-649 extends onto the study area.

3) CA-LAN-1740H was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site is an Euro-American solid fill bridge made of local sandstone blocks, mortar and concrete. It crosses Devil Canyon and is located within the southern portion of the Chatsworth Ridge Estates study area. Its age is unknown.

4) CA-LAN-1741H was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates as a scatter of Euro-American debris around the remains of three brick and mortar foundation pads. CA-LAN-1741H is located within the central portion of the subject property. Its age is uncertain although, due to the presence of iron rebar in the foundations, a post-World War II age seems most likely.

5) CA-LAN-1742H was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates and it consists of a stone retaining wall made of mortar and local cobbles, a concrete walkway, a fragment of fence line and introduced plants which include succulents and Eucalyptus. CA-LAN-1742H is located within the central portion of the study area.

In 1990 it was noted that the USGS topographical sheet showed a structure at this location, which had been demolished at the time of recording. This dates this structure to sometime before 1952 but after 1941, the date of the previous topographical sheet. The structure is also shown on the 1969 photo revision of the 1952

map, indicating that the destruction of it occurred between 1969 and 1990. It seems most likely that the structure was a post-World War II house or cabin of some kind. In 1990, this location was also noted as containing a substantial amount of contemporary construction trash and rubbish.

6) CA-LAN-1743 was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site measures approximately 10 by 10 meters and is believed to be a small, sparse lithic scatter consisting of four cultural items. CA-LAN-1743 is located within the southern portion of the study area.

7) CA-LAN-1744 was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site measures approximately 30 by 5 meters and appears to be another small, sparse lithic scatter, in this case consisting of only three cultural items. CA-LAN-1744 is located within the central portion of the subject property.

8) CA-LAN-1745 was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site measures approximately 15 by 10 meters and is apparently a third small, sparse lithic scatter, with a surface assemblage estimated at approximately 15 cultural specimens. CA-LAN-1745 is located within the central portion of the Chatsworth Ridge Estates.

Historical maps, consisting of the 1903 and 1941 USGS Santa Susana 15' topographical quadrangles, were also examined in an effort to identify historical structures or features that might have existed on the property. None were found to exist within the study area, per se, although there was development within the general vicinity by 1941, including the establishment of Twin Lakes Park, south of the study area..

4.0 ARCHAEOLOGICAL FIELD SURVEY

4.1 Field Methods

An intensive Phase I surface survey of the Chatsworth Ridge Estates study area was conducted by D.S. Whitley, Ph.D., and J.M. Simon between May 1 and 15, 2000. This was intended to assess the current status of the study area, to locate and record previously undiscovered archaeological sites, if any, and to assess the status of previously recorded archaeological sites.

Field procedures involved spacing the crew at approximately 15 to 20 meter intervals and then walking the property in transects, generally following the contours of the local topography. The ground surface was examined during these transects to identify archaeological specimens in the form of worked artifacts, or archaeological indicators, which might consist of specimens of shellfish, bone or waste lithic material resulting from the tool-making process.

During the survey special attention was paid to geomorphological conditions that affect the preservation of archaeological remains. Road or bank-cuts that expose subsurface stratigraphy, for example, along with stable geomorphic and depositional environments, were carefully examined for evidence of cultural remains. Given the geomorphology of the study area, these included the foots of slopes, as likely spots for subsurface deposition, and knoll tops and flat open ridges as areas also likely to contain cultural resources. Furthermore, rodent backdirt piles were carefully examined inasmuch as they can reveal the presence of buried archaeological deposits. In contrast, slopes of greater than about 25% grade, where erosional and gravitational forces would preclude the preservation of archaeological remains, were less intensively examined, both because of the negligible possibility that sites might be present on them, and for the safety of the crew members. In general terms, these areas were the steep canyon sides of Devil and Browns Canyons. In both cases, however, rock outcrops which might contain rockshelters or caves were examined for cultural remains.

4.2 Field Results

The Chatsworth Ridge Estates study area was found, in general, to consist of relatively undisturbed areas of native vegetation. Disturbance was primarily restricted to the mesa-like area towards the northern end of the parcel -- so-called Deer Lake Highlands -- where a series of dirt and paved roads and structures are or were once present. Currently, only one standing structure, an occupied house, is present on the property.

Field survey resulted in, first, the relocation and preliminary assessment of the previously recorded sites on the property. Our observations on and evaluations of these sites follow:

CA-LAN-209 - The portions of this site that are presumed to fall within the Chatsworth Ridge Estates study area were relocated and evaluated. However, we note that the precise location of the property line at this particular spot is not clear and a only few yards variance one way or the other may place a portion of the site inside or outside of the study area.

Those portions of the site currently thought to fall within the study area consist of three rockshelters and a boulder containing approximately 15 cupules and incised lines, all found within a small boulder field. Lithic debitage was noted within the rockshelters and intervening between them. A subsurface deposit is possibly present in and around these shelters. These site components appear to be intact and may be archaeologically significant. Again, however, precise mapping by a surveyor will be required before we can be certain that this site is within the Chatsworth Ridge Estates study area.

CA-LAN-649 - The southwestern portion of this site was confirmed to extend into the study area, as indicated by surface lithic artifacts consisting mostly of quartzite flakes and cores. The site is a quarry/workshop based on the exploitation of locally available metavolcanic and especially quartzite cobbles. It appears to be intact.

CA-LAN-1740H - This is a small solid fill-core, concrete and sandstone block bridge. No indications of the bridge's age could be found at the site, but it gives the appearance of potentially being old (i.e., pre-

twentieth century). In particular, cut sandstone blocks have been set with what appears to be lime mortar. Although it has suffered some damage from flood waters, it is primarily intact.

CA-LAN-1741H - This Euro-American site was relocated in the central part of the study area. As when originally recorded in 1990, it consists of red brick and concrete foundation pads that are rebar-reinforced, along with a scatter of rubbish and trash. Although the 1990 site record for this site states that "There is very little visible material on which to judge the age of the deposit," in fact this is a slight misstatement. The "artifactual remains" that are present at this location are easily datable, and they are all essentially contemporary in age. Although the age of the original constructions at this location may then very narrowly meet the minimum age criterion of 50 years (as would literally thousands of houses in the San Fernando Valley), this site clearly lacks integrity from an architectural perspective, having been reduced to foundations in the last few decades. Moreover, we could find no evidence of a historical archaeological deposit at this deposit, nor evidence sufficient to presume that such might be present.

CA-LAN-1741H does not, in our opinion, meet the criteria to qualify it as an archaeological site. And even if it arguably did meet such criteria, we can find no grounds for assuming that it somehow would meet the test of significance or uniqueness.

CA-LAN-1742H - This second Euro-American site, likewise in the central part of the study area, was also relocated and examined. It consists of a stone retaining wall, concrete walkway, part of a fence and remnant ornamental vegetation. "Cultural remains" present on this site, in addition to these features, are limited to contemporary trash and debris.

As with the previous site, it is at best dubious whether *CA-LAN-1742H* meets the minimum age criteria for eligibility as an archaeological resource, especially given that all associated "artifacts" represent contemporary rubbish. We could find no evidence to suggest that this location qualifies as a historical site, nor that it could meet the tests of significance or uniqueness.

CA-LAN-1743 - This site is a small, sparse lithic scatter located

within the southern portion of the study area. It was relocated and found to be intact.

CA-LAN-1744 - A second small, sparse lithic scatter was also recorded in 1990, in this case within the central portion of the study area. It was found to be intact when relocated during the current survey.

CA-LAN-1745 - The third small, sparse lithic scatter recorded in 1990 was also relocated. It consists of a quarry workshop and it is intact.

In addition to these previously recorded sites, two new archaeological site locations were identified and recorded. Sites records for these two new localities are included in Appendix B. They may be described as follows:

Archaeological site WS-1 - This site was recorded on 2 May, 2000, by Joseph M. Simon of W & S Consultants. The site measures approximately 150 by 75 meters and is a large stone tool quarry/workshop that contains a low density scatter of quartzite and volcanic cores, flakes, hammerstones and scrapers. WS-1 is located within the northern portion of the subject property. It appears to be intact.

Archaeological site WS-2 - The second site discovered on the Chatsworth Ridge Estates study area was also recorded on 2 May, 2000. The site measures 60 by 30 meters and consists of a small stone tool quarry/workshop that contains a low density scatter of quartzite and volcanic flakes. WS-2 is located within the northern portion of the subject property. It is intact.

5.0 CONCLUSIONS AND RECOMMENDATIONS

An intensive Phase I archaeological survey was conducted for the Chatsworth Ridge Estates study area, Los Angeles County, California. This involved background studies reviewing the prehistory, ethnography and historical land-use of the study area; an archival records search to determine whether any prehistoric or historical archaeological sites had been recorded or were known to exist on this property; and an intensive on-foot survey of the study area.

Background studies demonstrated that portions of the Chatsworth Ridge Estates project area had been previously surveyed and that eight sites had been recorded on it. Three of these sites were thought to be historical in nature. These are CA-LAN-1740H, -1741H and -1742H. The remaining five previously recorded sites, designated CA-LAN-209, -649, -1743, -1744, and -1745, are all prehistoric. On-foot survey of the study area resulted in the relocation and preliminary assessments of each of these sites. During this survey, two additional prehistoric archaeological sites were identified and recorded; these currently have the temporary designations of WS-1 and -2.

The seven prehistoric archaeological sites in the Chatsworth Ridge Estates study area are all intact and have the potential to be significant. Two of the three previously recorded historical sites, CA-LAN-1741H and -1742H, consist of the foundations of demolished structure that are associated with contemporary trash and debris. They appear to be post-World War II in age. While they possibly may just barely meet the minimum age requirement of 50 years for historical resources, as specified by CEQA, they are entirely lacking in integrity and thus have no significance from an architectural perspective. Moreover, they do not have any recognizable archaeological value. Based on these considerations, they are not considered significant cultural resources. The last historical site, CA-LAN-1740H, on the other hand, is a sandstone and mortar bridge which may be significant from historical, architectural or engineering perspectives.

5.1 Recommendations

Based on the presence of archaeological sites designated CA-LAN-209, -649, -1740H, -1743, -1744, and -1745, and W&S-1 and -2, development of the Chatsworth Ridge Estates property has the potential to result in adverse impacts to cultural resources. Following the guidelines of the California Environmental Quality Act (CEQA), we therefore recommend that Phase II test excavations and determinations of site significance be conducted on the seven prehistoric sites on the property, while a documentation and evaluation be completed on CA-LAN-1740H, the historical bridge. Such a program should be conducted in order to provide baseline data relative to the integrity and importance of each of these sites, from which final determinations of significance can be made, and final recommendations for the management of these resources can be offered.

RE: Records Search request for the Chatsworth Ridge Estates in Chatsworth, Los Angeles County, California

Dear Mr. Simon,

As per your request received on March 27, we have conducted an expedited records search for the above referenced project. This search includes a review of all recorded historic and prehistoric archaeological sites within a one-half mile radius of the project area as well as a review of all known cultural resource survey and excavation reports. In addition, we have checked our file of historic maps, the National Register of Historic Places, the California State Historic Resources Inventory, the California Points of Historical Interest, and the listing of California Historical Landmarks in the region. The following is a discussion of our findings.

PREHISTORIC RESOURCES:

Twenty-five prehistoric sites have been identified within a one-half mile radius of the project area. Three of these prehistoric sites are located within the project area (see enclosed map and site list).

HISTORIC RESOURCES:

Three historic archaeological sites have been identified within a one-half mile radius of the project area. All three of these historic sites fall within the project area (see enclosed map and site list).

Inspection of our historic maps – Santa Susana (1903 and 1941) 15' series – indicated that in 1903, the Southern Pacific Railroad was in place. A light street grid pattern was shown. There was a sparse scattering of structures. Devil Creek figured prominently. By 1941, urban development intensified and agricultural activity increased. Numerous structures were in place. State Routes 27 and 118 were shown. Twin Lakes Park, Iverson and Brandeis Ranches were all in place.

The California State Historic Resources Inventory lists no properties that have been evaluated for historical significance within a one-half mile radius of the project area.

The National Register of Historic Places lists no properties within a one-half mile radius of the project area.

The listings of the California Historical Landmarks (1990) of the Office of Historic Preservation, California Department of Parks and Recreation, indicate that there are no California Historical Landmarks within a one-half mile radius of the project area.

The California Points of Historical Interest (1992) identifies no properties within a one-half mile radius of the project area.

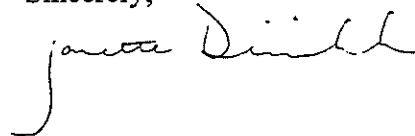

PREVIOUS ARCHAEOLOGICAL INVESTIGATIONS:

Forty-two surveys and/or excavations have been conducted within a one-half mile radius of the project area. Twelve of these investigations have been conducted within or adjacent to the project area (see enclosed map, report list, and bibliography). Nine additional investigations are located within the Oat Mountain quadrangle and potentially within the project area. These investigations are not mapped due to insufficient locational information.

Please forward a copy of any reports resulting from this project to our office as soon as possible. Due to the sensitive nature of site location data, we ask that you do not include record search maps in your report. If you have any questions regarding the results presented herein, please feel free to contact our office at (310) 825-1980.

Invoices are mailed approximately two weeks after records searches are completed. This enables your firm to request further information under the same invoice number. Please reference the invoice number listed below when making inquiries. Requests made after invoicing will result in the preparation of a separate invoice with a \$15.00 handling fee.

Sincerely,

Janette Dinishak
Information Center Staff

MANAGEMENT SUMMARY

Phase II archaeological test excavations and determinations of significance were conducted on sites CA-LAN-209, -649, -1740H, -1743, -1744, -1745, -2826 and -2827, Chatsworth Ridge Estates, Los Angeles County, California. This included mapping, surface collection and the hand excavation of test pits or augers on these site, as well as an analysis of the recovered archaeological assemblages, on the prehistoric sites, and documentation and analysis of the historical site. Two recorded sites (CA-LAN-209 and -649) were determined to have no intact components extending into the study area. Sites CA-LAN-1743 and -1744 were no longer extant at the time of the fieldwork. CA-LAN-1745, -2826 and -2827 were found to comprise low density, sparse surface lithic scatters. Fieldwork on them resulted in the recovery of all extant archaeological remains present at these locations. This has served to fully mitigate any adverse impacts that might result from the development of the project. Historical site CA-LAN-1740H is a bridge and dam built in approximately 1928. Examination of it demonstrated that it has experienced numerous cycles of storm damage and repair which has not been consistent with either original construction materials or architecture. From the perspective of historical resources it therefore lacks integrity and is not significant. Development of the Chatsworth Ridge Estates, therefore, will not result in adverse impacts to extant, significant cultural resources.

INTRODUCTION

1.1 Introduction

At the request of Mr. Richard Garlinghouse, The Presidio Group LLC, Phase II archaeological test excavations and determinations of significance were conducted at eight archaeological sites in the Chatsworth Ridge Estates study area, Chatsworth, Los Angeles County, California (Figure 1). These sites are CA-LAN-209, -649, -1740H, -1743, -1744, -1745, -2826 (W&S-1) and -2827 (W&S-2). With the exception of CA-LAN-1740H, a historical bridge, these sites are all prehistoric in nature. This project was intended to determine the size, nature and significance of these sites, and thereby to provide baseline data from which an assessment of potential adverse impacts to these resources could be made. These data have been employed to develop final management recommendations for the treatment of these cultural resources.

This study was conducted by W and S Consultants during August, 2000. Joseph M. Simon and David S. Whitley, Ph.D., served as principal investigators/project directors for the study; laboratory analysis was conducted by Tamara K. Whitley, M.A., and David S. Whitley, Ph.D.; this report was prepared by David S. Whitley, Ph.D., and Joseph M. Simon. Richard Angulo served as Native American monitor for the project, representing the California Indian Foundation.

The remainder of this chapter provides environmental and cultural background to the prehistory of the region, including a summary of previous archaeological research conducted in this region; and descriptions of the eight sites. This is followed by the field methods used at each, along with a summary of the field results. We then turn to an assessment of the recovered artifact assemblages. We conclude with final recommendations for the cultural resources within the Chatsworth Ridge Estates study area.

1.2 Environmental and Cultural Overview

1.21 Environmental Background

The Chatsworth Ridge Estates study area is located near the northwestern side of the San Fernando Valley (Figure 1), north of the Simi Valley Freeway (Highway 118), with the southwestern corner of the property at the intersection of this highway and Topanga Canyon Boulevard. This places it within the southern foothills of the Santa Susana Mountains. The study area can be described as a moderately sized mesa, the Deer Lake Highlands. Browns Canyon, on the east, and Devil Canyon, to the west and south, are the approximate limits of the study area in these directions. Roughly the northern half of the study area consists of the flat mesa like area, with elevation ranging from about 1300 to 1400 feet a.s.l., whereas the canyons on the periphery are steep and very rugged.

Historic and recent land-use changes have in some areas altered the environment from its status during prehistoric times. At least four major plant associations probably characterized the region containing the study area during the aboriginal period, however. These are chaparral, coastal sage scrub, southern oak woodlands, and riparian associations (cf. Muntz 1974).

The chaparral association covers steeper slopes with poorly developed soils and xeric conditions. It includes the following species: California sagebrush (*Artemisia californica*), white sage (*Salvia apiana*), black sage (*S. mellifera*), purple or white-leaved sage (*S. leucophylla*), California encelia (*Encelia californica*), California buckwheat (*Eriogonum fasciculatum*), scrub oak (*Quercus biberidifolia*), toyon (*Heteromeles arbutifolia*), mountain mahogany (*Cercocarpus betuloides*), lemonade sumac (*Rhus integrifolia*) and sugar sumac (*R. ovata*).

The coastal sage scrub community is the climax community for portions of inland coastal-southern California. It is generally composed of coast buckwheat (*Eriogonum cinereum*), although this species is absent in some of the inland valleys, and California buckwheat (*E. fasciculatum*), along with black sage (*Salvia mellifera*), sawtooth goldenbrush (*Hazardia squarrosa*), prickly phlox (*Leptodactylon californicum*), yucca (*Yucca* spp.) and California sagebrush (*Artemisia californica*) as major constituents.

The chaparral and coastal sage scrub communities are still present on the slopes of the study area, and were undoubtedly of subsistence importance to the aboriginal population of the region, the third association, the southern

oak woodland, may have been of primary significance in the inland zones adjacent to the coastal strip. This results because of the great importance placed on the acorn as a food staple by Native Californians (Kroeber 1925), and the rarity of this resource on the coastal side of the Santa Monica Mountains. The association is characterized by the coast live oak (*Quercus agrifolia*) and the valley oak (*Q. lobata*), but also would have included various species of native grasses. Although currently restricted in distribution, this association was once more widespread in the region. The open flats of the San Fernando Valley in fact, were once partly covered by oak woodland, and it is possible that the mesa like setting of the Deer Lake Highlands also may have contained this plant association.

The fourth and final plant association consists of riparian habitats, which are localized and poorly diversified woodlands found in areas of perennial moisture. They include such species as arroyo willow (*Salix lasiolespi*), mule fat (*Baccharis glutinosa*), curly dock (*Rumex crispus*), swamp knotweed (*Polygonum coccineum*), nettle (*Urtica holosericea*), cocklebur (*Xanthium strumarium*) and rabbit foot grass (*Polypogon monspeliensis*). Though this plant association is limited in distribution, it still had significant economic importance in aboriginal times, especially in terms of the acquisition of raw materials for items like baskets, cordage and netting. Riparian habitat would have been present in both of the canyons which border the study area.

The majority of the Chatsworth Ridge Estates study area continues to support native vegetation, with most of the existing disturbance within the study area localized in the Deer Lake Highlands area, proper. Here there are a few cleared and disked areas, an occupied house, and remnants of post-World War II structures along with a limited network of roads. Again, however, the majority of the study area is relatively undisturbed, reflecting in part the fact that portions of it are topographically rugged and isolated.

1.22 Regional Prehistory

The Chatsworth Ridge Estates study area is situated in a zone known prehistorically to have comprised a portion of the prehistoric Canaliño culture area (Rogers 1929; Wallace 1955), and historically to have been located just within the territory of the Fernandeno branch of the Gabrielino ethnolinguistic group (Kroeber 1925; Johnston 1962; Bean and Smith 1978). Our current understanding of the Canaliño prehistory is summarized below.

Canaliño prehistory was first defined in a chronological system established by D.B. Rogers (1929), working on the Channel Islands and the Santa Barbara

coastline. At a later date, Rogers' scheme was modified in terminology and improved with additional and more detailed data and radiocarbon dates by W.J. Wallace (1955), who applied it to southern California more generally. Subsequently, the Rogers/Wallace chronology had been successfully applied to inland Los Angeles County (e.g., McIntyre 1990), and is now recognized as having applicability to a wide area of mesic (i.e., that area west of the xeric desert zone) Los Angeles, Ventura, Riverside, San Bernardino and Orange Counties. Due to the widespread application of this chronological scheme, we employ Wallace's framework for the purposes of this study.

Late Pleistocene Period (Pre-10,000 years B.P.)

Wallace's chronology for southern California includes four time periods, the earliest of which (Early Man/Big Game Hunting period) was considered speculative, and was correlated with the end of the Pleistocene, or Ice Age. This would represent an occupation prior to about 10,000 years B.P. (Before Present). Although it is likely that inhabitation of the southern California coastal region occurred during this early time period, evidence for such is currently extremely limited. To date, Late Pleistocene archaeological remains in southern California comprise two kinds of evidence. First, in the inland Mojave Desert region, petroglyphs (rock engravings) and surface stone tools have been dated back to approximately 20,000 and 30,000 years B.P., respectively (Whitley and Dorn 1993; Whitley et al 1996). These may well reflect the initial human occupation of North America. The contexts of these dated finds provide only limited kinds of archaeological information and, while there is much more to be discovered about this earliest prehistoric culture, existing data nonetheless suggest that these earliest inland Californians may have dwelled along the shores of Pleistocene lakes; that they exploited chert quarries to make relatively crude stone chopping tools; and that they also made rock art, perhaps as part of shamanistic religious practices.

Second, a limited number of large fluted projectile points have been found in isolated locales in the Mojave Desert and along the California coast. These projectile points functioned as parts of spears and are known to date between 11,200 and 10,000 years B.P., falling within what is called the Paleoindian Period on the Great Plains. On the Plains, such points are associated with the hunting of extinct Pleistocene fauna, such as the Columbian Mammoth. Although it is likely that these spear points were similarly used in southern California, the isolated nature of the discovered artifacts precludes any certain inference about their use or function in the California region.

Uncertainty concerning these early prehistoric cultures results from the

characteristic geomorphological instability of the California coastline and the general youthfulness of the southern California interior, combined with the major change in erosional/degradational regimes that occurred at the end of the Pleistocene (Whitley and Dorn 1993). Each of these factors does not favor the preservation of remains from this period. It is therefore likely that Late Pleistocene human occupation of Los Angeles is under-represented in the local prehistoric record, simply due to problems in site preservation.

Early Millingstone Period (10,000 - 3500 years B.P.)

With the transition towards a modern environment, starting approximately nine to ten thousand years ago, an adaptation referred to as the Early Millingstone Period or Horizon began. This is particularly evident along the coast, where many such sites are found, although a few examples are known from the inland region. Most sites of this stage date between 8500 and 3500 years in age.

Recent studies by Erlandson (1988; see also Erlandson and Colton 1991) provide evidence of a significant, even if small, population of coastal hunter-gatherers in the region before 7000 years ago, or essentially at the beginning of this Early Millingstone period. He has shown that these were neither Big Game hunters, nor specialized, hard-seed gatherers, but instead generalized foragers that relied on a variety of different kinds of terrestrial, coastal and marine resources, and that they were adapted to estuarine embayments that have long since disappeared from the local environment. Further, his evidence indicates that their primary protein sources were shellfish and other marine resources. Extending a pattern first identified by Meighan (1959) on the Channel Islands, in other words, this suggests that the adaptation to the seashore is a very ancient and long-lived tradition in local prehistory.

In the inland region, perhaps the earliest evidence of the Early Millingstone Period is provided by so-called Los Angeles Woman, a female skeleton found in the La Brea Tar Pits which has been radiocarbon dated to 9000 years B.P. Lacking clearly associated artifacts or other remains, it is difficult to interpret the Los Angeles Woman beyond observing simply that her discovery signals the fact that the inland region was in use shortly after the end of the Late Pleistocene.

Later Early Millingstone sites (post-dating approximately 6000 years B.P.) are dominated by assemblages containing large numbers of groundstone artifacts, along with crude choppers, scraper planes, and other core/cobble tools. These are thought to represent an adaptation to gathered plant foods, especially a reliance on hard-shelled seeds. Accordingly, it has been common

practice to identify any site with a dominance of these plant processing implements as Early Millingstone in age. More recently, it has also been suggested that scraper planes, in particular, may have served in the processing of agave (Kowta 1969; Salls 1985); that the association of groundstone and core/cobble tools represents a generalized plant processing toolkit, rather than one emphasizing hard-seeds, per se (Whitley 1979), and that this toolkit was used in appropriate environmental settings throughout the prehistoric past. That is, that the so-called millingstone toolkit is environmentally rather than chronologically specific and reflects localized exploitative patterns, rather than a chronologically specific adaptational strategy (Kowta 1969; Leonard 1971; McIntyre 1990). Thus, many inland sites identified as dating to the Early Millingstone Period solely on the basis of their groundstone toolkits may, in fact, not be of such age at all. However, on the coastal strip there continues to be evidence that such sites date to the earlier end of the time-frame. These sites are generally located on terraces and mesas, above the coastal verge, near permanent streams.

Although Early Millingstone period sites are relatively common along the coast, there is little evidence for the occupation of the inland region during this early time period. That is, although the millingstone adaptation to seeds and plants, and toolkits dominated by plant processing tools, are present in the inland zone, they appear to date to a later time period, with true Early Millingstone period occupation apparently restricted to the coastal strip, proper (Whitley and Beaudry 1991; cf. Leonard 1971; McIntyre 1990). Again, it is currently unclear whether this pattern reflects real differences in inland versus coastal settlement distributions, or is simply a function of site preservation problems in the inland region. Whatever the cause, it is worth noting that there are currently very few reliable or plausible chronometric dates from inland sites that are Early Millingstone in age. All current temporal assignments of inland sites to the Early Millingstone period are based on putative diagnostic artifacts but, when these are examined critically, the verity of the early age assignments become dubious. And, too often, such early age assignments are based on functional/adaptive traits rather than stylistic criteria, thus confusing adaptive patterns for temporal ones.

A good example of the confusion of millingstone functional and adaptational patterns for Early Millingstone chronological diagnostics in inland Los Angeles County is provided by the so-called "Topanga Culture", as exemplified by excavations at CA-LAN-1, the "Tank Site" (cf. Heizer and Lemert 1947; Treganza and Malamud 1950; Treganza and Bierman 1958), located in the Santa Monica Mountains immediately south of the San Fernando Valley. This is widely regarded as "Early Millingstone" chronologically, and its base

("Phase I") has been assigned 10,000 years of age, essentially due to the large numbers of millingstones, crude choppers and "cog stones" (see Treganza and Bierman 1958:75, Table 1). But, as Johnson (1966) has rightly pointed out, Phase III of the Topanga Culture is only 3000 years old, as demonstrated by his excavations at CA-LAN-2. That is, it is Intermediate and not Early Millingstone in age. It then must follow that the preceding Phase II can only be considered 3500 to 3000 years old, due to the presence of (Intermediate period) mortars and pestles in the Phase II assemblage. That is, Phase II of the Topanga Culture also can only be Intermediate period in age. Since Phase I lies conformably and immediately below Phase II stratigraphically, it likewise must follow that it immediately predates the Intermediate period Phase II remains. At best, then, Phase I of the Topanga Culture is terminal Early Millingstone or transitional Early Millingstone/Intermediate, but not necessarily of any great antiquity.

This fact is emphasized when it is recognized that one of the key classes of temporal diagnostics said to support the very early age assignment for Phase I at the Topanga Site, the cog stones, were all recovered from the Phase II deposit, even though Treganza and Bierman (1958) incorrectly assign them to the Phase I assemblage (Eberhart 1961:366-7). Thus, there is currently no evidence to suggest any great antiquity for Phase I of the Topanga culture; instead it may simply be 4000, rather than 10,000 years in age, and may represent an early manifestation of the Intermediate Period movement of a millingstone adaptation into the interior, rather than a manifestation of a coastal Early Millingstone culture in the inland zone.

Intermediate Period (3500 - 800 years B.P.)

As implied above, a transitional stage followed the Early Millingstone, which is referred to as the Intermediate Period (Wallace 1955). It is believed to have begun about 3500 years ago, and to have lasted until about A.D. 1200 (according to the latest revisions; cf. Arnold 1987). It is marked on the coast by a growing exploitation of marine resources, the appearance of the hopper mortar and stone bowl/mortar, and a diversification and an increase in the number of chipped stone tools. Projectile points, in particular, are more common at sites than previously, while artifacts such as fish hooks and bone gorges also appear.

As noted above, cog stones also first appear during the Intermediate Period, although they are widely misinterpreted as Early Millingstone in age. These are relatively small, flat cobbles, about the size of a large biscuit, that were shaped to resemble a kind of mechanical cog or gear. Although the function of these is unknown, it is likely they served as ceremonial objects, and their

geographical distribution has an important implication for regional prehistory. As first identified by Eberhart (1961), cog stones are only found from Los Angeles County south and eastward; that is, they are absent in the areas of the Santa Barbara Channel region (Ventura and Santa Barbara Counties) that, historically, were occupied by Chumash speaking groups. Although speculative, this suggests that the initial distinction between the Hokan Chumash and Takic speaking groups (which included the Gabrielino) may have developed as early as 3500 years ago (cf. Kowta 1968:50; McIntyre 1990:5), rather than only 1500 years B.P., as Kroeber (1925) first hypothesized. That is, the distribution of these "ceremonial" artifacts essentially follows the boundaries of ethnolinguistic groups during the historical period, suggesting that such boundaries may have been more-or-less stable for about 3500 years. Notably, this hypothesis is supported by excavations at Intermediate Period site CA-LAN-2233, in the Santa Clara River Valley to the north. At this site, osteometric and DNA analyses indicate that the resident population was non-Chumash genetically (Waugh 1999).

As also implied above, there is growing evidence that it was at the beginning of this Intermediate Period that inland sites, such as those found in the Conejo area on the north side of the Santa Monica Mountains, the upper Santa Clarita Valley, the Antelope Valley, and western Riverside and San Bernardino Counties, were first established and occupied. Whether this pattern holds for the interior Los Angeles Basin, including the San Fernando Valley, has yet to be determined but seems likely. This suggests the exploitation of more varied environments and perhaps an increase in population at this time and, again, it may correlate with Kroeber's "Shoshonean Wedge" moving into mesic southern California at circa 3500 years B.P. (Whitley et al n.d.; cf. Whitley and Beaudry 1991). In general, however, the Intermediate Period can be argued to have set the stage for the accelerated changes that took place immediately following it.

Canaliño/Late Prehistoric (800 to 200 years B.P.)

With the transition to the Canaliño or Late Prehistoric period at A.D. 1200, we can correlate local prehistory with the ethnographic societies as described (even if in abbreviated form) by early chroniclers and missionaries. However, this is not to suggest that local societies and cultures were in any way static, for the transition to the Canaliño period was marked by the evolution and eventual dominance of a sophisticated maritime economy. Further, among the Chumash to the west, a rise in social complexity has been shown to have been associated with the development of craft specialization, involving the use of standardized micro-drills to mass produce shell beads on Santa Cruz Island (Arnold 1987), which occurred during this period. This,

apparently, contributed if not caused the appearance of a simple chiefdom in the southern Chumash region (cf. Whitley and Clewlow 1979; Whitley and Beaudry 1991).

Although we do not have evidence that the Gabrielino developed into a chiefdom like the neighboring Chumash, the Canaliño period nonetheless witnessed a florescence of local aboriginal culture paralleling the Chumash case. This included a substantial growth in population, the establishment of permanent settlements on the coast (and probably at favored locales in the inland area), a high degree of sociopolitical complexity, and the development of a very sophisticated maritime economy. It was during the Canaliño period, thus, that the occupants of the Santa Barbara Channel and Los Angeles County region achieved levels of cultural and social sophistication perhaps unrivaled by hunter-gatherer-fisher groups anywhere else in the world (Wallace 1955; Johnston 1962; Landberg 1965; Brown 1967).

1.23 Ethnographic Background

As noted above, the study area falls within the ethnographic territory of the Takic speaking Gabrielino; specifically, of the Fernandeano dialect of Gabrielino. "Fernandeano" and "Gabrielino" are terms of Spanish derivation, resulting from the standard missionary practice of naming indigenous peoples after the mission to which they were attached, in this case the Missions San Fernando Rey and San Gabriel Arcangel, respectively. True indigenous names for the Gabrielino included *Kij* or *Kizh* (Johnston 1962; Reid 1968), the etymology of which is unknown; *Kumivit*, "easterner"; and *Tobikhar*, etymology again unknown (Bean and Smith 1978:548), although it is not clear that any of these terms were actually employed by the Gabrielino as self referents (see below). In contrast, the Fernandeano were known to the Gabrielino as *Pasekwarum*, from *Pasekngna* (referring to a village near the San Fernando Mission). Thus, although "Gabrielino" and "Fernandeano" are in some senses inappropriate, they continue in standard usage.

Regardless of appellation, what historically have been referred to as the Gabrielino extended from Orange County north through the Los Angeles Basin to the crest of the San Gabriel Mountains, including the headwaters and watershed of the San Gabriel River, and from the coast eastward to include Mt. San Antonio (Mt. Baldy) and western Riverside and San Bernardino Counties. To the west, Gabrielino territory extended to Topanga Canyon, and included the San Fernando Valley (Kroeber 1925: Plate 57; Johnston 1962; Bean and Smith 1978a:538). Fernandeano was spoken primarily if not

exclusively within the confines of this large inland valley.

According to Bean and Smith (1978a:538), the Gabrielino were culturally extinct by the beginning of this century -- that is, prior to the recording of any detailed ethnography on them -- various sources, and analogies with better known surrounding groups, can be employed to reconstruct aspects of their ethnographic lifeways. For example, the Gabrielino and the linguistically related Serrano shared many, if not most, cultural traits (Kroeber 1925:578-580; Bean 1972:69, 1978:575-576). We base the following reconstruction, accordingly, on Gabrielino, Serrano and Cahuilla sources (e.g., for the Gabrielino, see Dakin 1939, Reid 1968, Kroeber 1925, Johnston 1962, and Bean and Smith 1978a; for the Serrano, see Benedict 1924, Kroeber 1925, Strong 1929, and Bean and Smith 1978b; for the Cahuilla, see Barrows 1900, Kroeber 1908, 1925, Hooper 1920, Strong 1929, Bean 1972, 1978; and Bean and Saubel 1972, etc.).

The terms "Gabrielino" and "Fernandeño" strictly apply to groups of people united only by the use of a dialectical variant of the Gabrielino language (itself a Cupan language of the Takic branch of the Uto-Aztecan linguistic family). That is, they imply no necessary sociopolitical unity (as in a single 'tribe') and, in fact, a series of different political units may have existed among the Gabrielino at the time of Spanish contact, explaining why there were no generic terms for these groups as unified corporate units. Further, there may have been as many as six dialectical variants of the larger Gabrielino language (Kroeber 1925:620), the best known of which was Fernandeño (cf. Englehardt 1927).

Based on these ethnographic sources combined with early Spanish accounts, we may confidently infer that the inhabitants of the San Fernando Valley region were hunters-gatherers, with subsistence emphasizing acorns, yucca, juniper berries, sage seeds, mesquite, pinyon and islay and other plant resources. Following a sexual division of labor common throughout native California, women were principally responsible for the acquisition and preparation of plant foods. Game was also hunted, with small animals, such as rabbits/hares and rodents, probably representing more significant contributions of meat protein than larger game, such as deer. Women and children contributed to the hunting (often with nets and drives) of the smaller game. The large game, however, was the exclusive domain of the adult male hunters. Also following practices common throughout the state, specific resources exploited at any given time were a function of what was then seasonally available. Since this was somewhat a function of time of year and elevation, a pattern of transhumance was followed, indicating that only a

few of the local villages (exclusive of those on the coast) would have been inhabited year around. Instead, inhabitation followed a pattern of population aggregation into large villages, usually during the Fall/Winter, when stored resources like acorns and pinyon nuts were eaten, and dispersal into single family units, typically during the Spring/Summer, when resources were more widely distributed.

It is likely that Gabrielino inhabitants wintered in large villages near permanent water sources on the Los Angeles Basin floor, whereas the Fernandefio would have occupied similar villages at springs on the San Fernando Valley floor or foothill edges. Upland zones, such as are found in the San Gabriel and Santa Susana Mountains to the north and the Santa Monicas to the south, would have been exploited seasonally, during the Spring, Summer and Fall, when valuable plant species ripened (e.g., on the northern slopes, pinyon nuts in the fall). Small, single family camp-sites would have been established near to the plant resources at this time. The highest elevations of the mountains, comprising pine forests, would probably only have been usable for hunting, with only minimal camp-sites established.

Social and political organization can be assumed to have been similar to the well described systems of the Cahuilla (see Strong 1929; Bean 1972, 1978). These involved patrilineal moieties and clans of three to ten lineages that served as political-ritual-corporate units (Bean 1978:580). Each lineage maintained a village site and resource exploitation area. The office of the ceremonial leader was usually restricted to the founding lineage of the clan, which also owned the ceremonial house and ceremonial bundle. Each lineage had its own lineage leader who served in a variety of sacred and secular capacities, and who met with other such leaders to adjudicate inter-lineage disputes. This office was hereditary and patrilineal. He was assisted in many tasks and responsibilities by a *paxa*, or assistant, also an inherited office. Ceremonial song leaders also aided in ritual activities (ibid).

It is also likely that religion followed the patterns found among surrounding groups. In this case, shamanism would have functioned as the central element. This posits a direct and personal relationship between each individual and the supernatural world, with this relationship enacted by entering a trance or hallucinatory state (usually based on the ingestion of psychotropic plants, such as jimsonweed and, especially, native tobacco). Shamans, per se, were considered individuals with an unusual degree of supernatural power, and served as healers or curers, diviners, and controllers of natural phenomena (such as rain or thunder). Shamans are also known to have produced the rock art of this region, which depicted the hallucinations

and spirits they observed in their vision quests. In addition, however, rock art was also painted by male and female initiates at the conclusion of a puberty ritual. Importantly, this initiatory art was also intended to display the spirit helper the initiate received during these ceremonies. Thus, two kinds of ethnographic rock art can be expected in the region: sites owned and made by shamans, and sites used for village initiations (Whitley 1992, 2000).

Given the early disruption of aboriginal lifeways in historical times, it is not surprising that little in the way of information about historical villages and aboriginal place names has been recorded for Gabrielino and Fernandean territory. However, the exploration and settlement of the San Fernando Valley region did result in the recording of a small number of place-names. As noted above, *Pasekngna* was a village near the San Fernando Mission, while *Achoicomina* was the location of the mission itself. *Tuhungna* was a village located on the north bank of Big Tujunga wash, while *Muhungna* served the same purpose near the mouth of the Little Tujunga. *Tongva* was another village name in the Tujunga area, and was sometimes used to refer to the residents of this area, while *Kawengna* contributed its name to the Cahuenga Pass.

1.24 Historical Background

Local history may be best considered with reference to three periods: Spanish, Mexican, and American. These are discussed below in turn.

The Spanish Period (A.D. 1542 - 1821)

Initial contact between the indigenous Gabrielino and the Spanish occurred in October, 1542, with the arrival of Juan Rodriguez Cabrillo along the Los Angeles County coast. This was followed in 1602 by the Vizcaino expedition, which landed on Catalina Island and visited local inhabitants there (Bancroft 1963). As exploratory expeditions, the early Spanish sailors' impact on the Gabrielino is difficult to gauge: while they clearly resulted in no permanent European settlements and made no consequential forays into the interior, it is nonetheless possible that they may have introduced diseases with widespread deleterious effects on the local population.

Substantial contact between inland Gabrielino and the Spanish did not occur for over two-hundred years after Rodriguez Cabrillo's initial foray. This event was the arrival of the overland party of Don Gaspar de Portolá in the Los Angeles Basin in 1769, preparatory to the establishment of a Spanish colony in the region (Brandes 1970; Bolton 1971; Boneau Companys 1983).

Subsequent to a stop at what would become the pueblo of Los Angeles, Portolá and his men passed through the San Fernando Valley before preceding northwards to the Santa Clara River Valley and then turning west to the sea. Called the "Encino Valley" when the expedition visited it on August 5 and 6, 1769, the San Fernando Valley was christened *Santa Catalina de Bononia de los Encinos* by Father Crespi, chaplain of the expedition.

Following Portolá's expedition, Spanish settlement of Upper California was initiated with the establishment of a series of missions, presidios (forts), and pueblos (towns). Mission San Gabriel Arcangel, in 1771, was the fourth mission founded in Upper California, and represented the first Spanish settlement in the greater Los Angeles area. With the appointment of a military governor, Felipe de Neve, in 1775, Spanish efforts to establish civilian settlements independent of the missions were also initiated. De Neve selected a possible site for such a pueblo on the Porciuncula (later Los Angeles) River in 1777 and began the process of enlisting settlers to inhabit it. These were derived from colonies in Sinaloa and Sonora and included settlers of Native American, African and Spanish descent, as well as various admixtures thereof. In all, 11 families comprising 44 individuals settled the newly founded pueblo, arriving between June and October, 1781. *Nuestra Señora de la Reina de los Angeles de Porciuncula*, as the new town was called, was officially chartered on September 4, 1781, shortly before all of the settlers had arrived (Bancroft 1963; Robinson 1981). This was the origin of what would become the City of Los Angeles.

The growth of the pueblo was relatively rapid, with population more than tripling to 139 by 1790 - that is, in less than ten years - with 29 adobe residences constructed, a town hall, barracks, bodega (municipal storehouse), and a surrounding adobe wall. This growth was aided by the establishment of ranchos, or large ranch concessions, the first three of which were granted in Los Angeles County in 1784.

Settlement and use of the San Fernando Valley, somewhat isolated from the growing pueblo by the Hollywood Hills (the eastern extension of the Santa Monica Mountains), however, lagged behind the growth of the pueblo itself and the Los Angeles Basin to the south. The initial Euro-American entrants into the valley were apparently illegal users of the lands, the rights to which were retained under Spanish law by their Native American occupants unless and until they were formally awarded by the government to non-Indian recipients. Records on these early Euro-American squatters are close to non-existent, as might be expected. One who has entered the record and who figures directly in the history of the valley, however, is Francisco Reyes.

Reyes arrived in California from Mexico in 1787, built an adobe in the pueblo of Los Angeles, and was alcalde (mayor) there between 1793 and 1795. He also built a house on an illegal ranch he was operating in the San Fernando Valley at this same time. He and one Comelio Avila kept their livestock at this ranch, which shortly thereafter became the foundation for the Mission San Fernando (Engelhardt 1927:140-141; 1930:509-513). The early Euro-American history of the San Fernando Valley is necessarily tied to the development and decline of this mission, even though it does not fall within the current study area, per se.

The decision to build a mission in the San Fernando Valley was reached in 1797, when ecclesiastical authorities recognized a need for a mission intermediate between San Gabriel and San Buenaventura (Ventura). An expedition was sent out at that time to locate a favorable spot for such an establishment. After scouting locales in the Simi, Santa Clara and Conejo Valleys, Reyes' Ranch with its nearby Fernandeño village of *Achois Comihabit* (rightly, probably "*Comihangna*") was visited and chosen as the preferred spot. Father Vicente de Santa Maria, chaplain to this expedition, noted that: "To this village belong, and they acknowledge it, the gentiles of other rancherias, such as *Taapa, Tacuyama, Tucuenga, Juyunga, Mapipinga*, and others, who have not affiliated with Mission San Gabriel" (quoted in Engelhardt 1927:5). Even at this early date, then, it appears that Native American settlement had been disrupted, and inhabitants of distant villages were congregating in newly formed aggregations. This set the stage for population distribution during the mission period in the valley, per se: the further aggregation of Fernandeño, Tataviam and some Chumash peoples into a single settlement, based on a corporate system of agricultural production.

The dedication and then construction of the mission followed closely thereafter. On September 8, 1797, Father Fermin Lasuen dedicated the mission and baptized ten children (Engelhardt 1930:513). It was named San Fernando Rey in honor of King Ferdinand V, at the request of the Spanish king, Charles IV (Thompson and West 1880:104). Father Francisco Dumetz (1743 - 1811) served as first pastor at San Fernando.

Dumetz had been born in Majorca, Spain, and first arrived in California in 1771, bringing with him the first sheep introduced into Upper California. He presided over nearby Mission San Buenaventura from 1782 to 1797 before being put in charge of San Fernando. At San Fernando he was responsible for erecting the initial buildings, building the second church and quadrangle and the so-called Christian village, and for starting the third and final church, begun in 1804. He was reassigned to Mission San Gabriel in 1805, where he

died in 1811 (Geiger 1969:66-69).

Dumetz established a stable institution which expanded in size and influence over the next few years. This included the development of the *Asistencia* (or sub-mission) of San Francisco Xavier, in the Santa Clara Valley, in 1804. This served both ecclesiastical and economic needs, as it provided a religious center for Native Americans living in the Newhall area, as well as access to additional grazing and farming lands for the growing mission population. Growth and stability of the mission was not, however, continuous during the Spanish period. In 1810 Mexico declared independence from Spain. This was not gained for another eleven years but, during this decade, economic conditions deteriorated radically. Soldiers and priests, for example, were essentially not paid, and the missions were forced to contribute to the upkeep of the local Mexican government (Englehardt 1927:35). Because of this disruption the mission system to begin to fray, although circumstances deteriorated much more rapidly once independence was achieved.

The Mexican Period (A.D. 1821 - 1848)

With Augustin de Iturbide's *Plan de Iguala*, proclaimed on September 16, 1821, Mexico finally achieved independence from Spain. Shortly prior to independence, however, a new pastor was assigned to Mission San Fernando, Father Francisco Gonzalez de Ibarra. Gonzalez de Ibarra had the unfortunate luck to run the mission during its greatest and most devastating period of decay: 1821 to 1835.

Gonzalez de Ibarra (1782 - 1841) was born in Navarre, Spain, arriving in America in 1819. He was first assigned to Monterey in 1820 and was transferred to San Fernando in 1821. Prior to his arrival, Mission San Fernando had been responsible for 2442 baptisms from the period of 1797 to 1820, averaging over 105 per year. During Gonzalez de Ibarra's 14 year tenure baptisms totaled only 412, dropping to an average of less than 30 per year. Similarly, the mission's herds of cattle dropped from a high of about 12,000 to approximately 7,000; while sheep were reduced from 7,600 to around 4,000 (Geiger 1969:110-111). These conditions resulted from the increasing financial demands made by the civil government on the missions and the resulting stress this placed on the indigenous population. Shortly after Mission San Fernando was secularized by the government in 1834, Gonzalez de Ibarra was so dispirited by these conditions that he fled California for Sonora, abandoning his ecclesiastical post without permission from his superiors. Although this act was sufficiently grievous to warrant defrocking, his superiors recognized the very unusual circumstances which precipitated it and, following the reversal of secularization, allowed him to

return to California where he eventually died, in good graces, at Mission San Luis Rey (*ibid*).

Gonzalez de Ibarra was, however, a good administrator regardless of the difficult circumstances under which he was given his charge. The result was that even in its decline Mission San Fernando was one of the healthier of the California missions, and so was coveted by civil authorities as the mission system waned. The first formal step in this process (aside from the increasing demands to provide financial support to the civil government and military) was an 1827 decree requiring the missions to define their lands and assets. The San Fernando Mission declaration listed its domain as stretching 10 leagues from Cahuenga to Triunfo and northwards for five leagues to Camulos on the west and San Francisco Xavier on the east. It also declared that it was raising wheat, corn and beans and had about 6,000 cattle and 8,000 sheep at that date (Englehardt 1927:47).

The next formal action in the disbanding of the missions occurred in January, 1833, when Governor Jose Figueroa signed an act "secularizing", which is to say confiscating, the missions. Lt. Antonio del Valle was commissioned in 1834 to secularize San Fernando and, in 1835, was assigned to serve as mayordomo or administrator over its operations (*ibid*:50). He inventoried the mission holdings, recording that they included \$5,700 in various assets, 32,000 grapevines and 1600 fruit trees, with a native population of 541. Del Valle also recorded that considerable difficulty was occurring with this native population, who according to him were responsible for constant thefts of horse and cattle (*ibid*:50-51). The Native American population had apparently recognized by this time that their best recourse was to retreat to more remote spots, taking with them some of the livestock and produce which they had spent their lives raising and growing. Still, some of them stayed on as the mission was reduced to the status of a parish. In 1839, when the Asistencia de San Francisco Xavier was removed from the mission and awarded as a rancho to del Valle, San Fernando still retained 416 Indian inhabitants, all of whom presumably worked as agricultural laborers for the new secular administrators (*ibid*:59).

Further dissolution of the mission system occurred in 1845 when Governor Pio Pico proclaimed that mission lands would either be sold by the civil government, or leased to individuals for commercial use. Pico's brother Andres and Juan Manso were awarded a nine year lease for San Fernando, at a term of \$1,100/year, in 1846 (*ibid*:64-65). However, the ensuing war with the United States put a financial strain on the government, requiring Pico to sell the leased San Fernando mission lands to Eulogio de Celis for \$14,000,

with the nine year term of Andres Pico and Manso still intact (Robinson 1961:12). Total land included in this sale was 13 square leagues, exceeding any previous land transfer in California because this sale was not constrained by the size restrictions placed on the award of rancho grants.

The American Period (A.D. 1846 -)

The American Period brought great changes to the San Fernando Valley but, unlike other regions within suburban southern California, this did not involve a continuous and relatively quick evolution from a large mission tract to the modern suburbanized and urbanized valley which exists today. For the southern half of the valley, in particular, the history of change in land-use comprised an initial phase of large-scale agricultural use (1846 - 1888) followed by a period of subdivision into small farms and ranches (1888 - 1940), followed ultimately by the suburban development evident today (1940 - present). The northern and especially northwestern areas, including the study area *per se*, were developed much later. These phases may be considered in turn.

With the transition to U.S. control of California an initial governmental concern was the examination and, where appropriate, validation of preexisting rights to land ownership. A Lands Commission was appointed in 1851 to hear lawsuits concerning contested lands. Among the first of those heard involved the mission lands, resulting from an action instituted by Bishop Jose Alemany in 1853. The civil possession of Mission San Fernando was determined illegal by the commission, and the mission buildings and lands immediately surrounding them (about 170 acres) were patented back to the Catholic Church in 1862. By this point, however, the mission was essentially in ruin.

The remaining Ex-Mission San Fernando lands stayed in civil hands, specifically under de Celis' ownership, albeit he (or, more rightly, his heirs) did not receive clear title in the form of a US patent until 1873. Moreover, he sold an undivided half interest to Andres Pico in 1854 for \$15,000. Pico continued to use the land for cattle ranching, as he had under the terms of his former lease with the Mexican government. Pico subsequently sold his holdings to his brother Pio in 1862. Pio Pico, like many other Californians, suffered greatly from the droughts of the 1860s, causing him to mortgage his property to a New York bank. In 1869 he sold these mortgaged lands to the San Fernando Farm Homestead Association for \$115,000 (Dumke 1944:98-99; Jorgensen 1982:85). This group got the Ex-Mission lands partitioned from de Celis' heirs, taking as their share about 60,000 acres which constituted the southern half of the valley (Robinson 1961:21). This

represented an investment of less than \$2/acre for the area that would one-day become North Hollywood, Van Nuys, Reseda and Canoga Park.

The financier behind the San Fernando Farm Homestead Association was Isaac Lankershim, a Bavarian who had become rich as a grain farmer in northern California. Lankershim hired Isaac Newton Van Nuys to manage his newly acquired holdings, which they quickly put into livestock and then wheat production. Their first two years of farming were unsuccessful, largely because they had no ready means to ship their grain to port. The Southern Pacific Railroad, however, began the north-south rail route from Los Angeles to San Francisco in 1873 by laying 25 miles of track north out of Los Angeles. This first stretch of tracks (running through the area of modern Burbank) terminated at a townsite in the northern half of valley which was named San Fernando, after the mission. SPRR also extended a line from Los Angeles south to the port at Wilmington (Nadeau 1965:81-82). The establishment of the northern rail line directly led to the beginnings of development in the San Fernando Valley, albeit initially this was restricted to the northern half, some distance away from the East-West Transportation area study area.

The San Fernando line, still, provided the means for making Lankershim's large scale wheat farming economically successful. Initially, however, he and Van Nuys had to go to the effort and expense of constructing a wagon road across the Sepulveda Pass as a leverage to get the SPRR to give them a reasonable freight rate from their valley sidings to the wharves at Wilmington. Once these arrangements were worked out, truly massive farming began, with 10,000 acres seeded in wheat in 1875 (Nadeau 1965:89).

Lankershim's San Fernando Farm Homestead Association was succeeded by the Los Angeles Farming and Milling Company in 1880 in what looks largely like a paper transfer, name change, and minor reshuffling of investors; common usage still termed the property the "Lankershim Ranch" into the early 1900s (e.g., *Los Angeles Daily Times*, September 24, 1909, page 1). Large-scale farming, intended for the world market, continued into the late 1880s, when the world wheat supply exceeded demand and the price per bushel began to decline steadily (Jorgensen 1982:82). This led to the second phase of the American land-use history of the valley: a shift from large scale agriculture towards sub-division and the development of small-holdings.

This process began in 1888 when Lankershim divided off and bought outright for himself 12,000 acres of the Los Angeles Farming and Milling Company holdings in the east end of the valley (extending west to about Whitsett Avenue). With this he created the Lankershim Ranch, Land and Water

Company (Dumke 1944:99). With his son J.B. he subdivided this into small ranches and farms, selling them for \$5 to \$55 per acre. The population center for this development was a townsite located along the road running from Cahuenga Pass to San Fernando (near the corner of what is now Lankershim and Tujunga Blvds.), which they named Toluca. Subsequently the name of this town was changed to Lankershim and finally North Hollywood, when the local merchants decided there was something to gain by hitching their name recognition to the developing allure of Hollywood. Toluca failed to grow into a large settlement during this early period, although a hotel, school, some stores and several houses were built at this locale shortly after it went on sale (ibid). Still, Lankershim realized \$200,000 in land sales in 1888, and the value of his land apparently went up rapidly. A front-page advertisement in *The Times* of April 7, 1889, for example, states the following:

LANKERSHIM RANCH LAND AND WATER COMPANY - 12,000 Acres: Finest San Fernando Valley Lands, 10 Miles Northwest of Los Angeles on Main Line of the Southern Pacific Railroad, Now Offered in Tracts of 5, 10, 20 and 40 acres, \$35 to \$165 per acre! Terms, One-quarter cash. Balance 1, 2 and 3 years. Deferred payments bear interest at 7 per cent per annum.

Similar subdivisions were established in other parts of the valley, notably, the northern half, but one factor greatly impeded the development of small farms: an absence of water.

Due to complicated water rights, ultimately tied to the founding of the pueblo of Los Angeles under Spanish law, an 1881 California Supreme Court Decision held that all of the water in the San Fernando Valley belonged to the City of Los Angeles. Valley residents were therefore denied access to the surface water in the Los Angeles River, and they were denied the right to drill wells. Confounding matters even more, because these farms were situated outside of then existing City of Los Angeles limits, the city could not legally sell water rights to them. Although Los Angeles was relatively slow to enforce its rights, between 1900 and 1905 it instigated proceedings against 200 valley farmers and ranchers (Jorgensen 1982:140-141). This circumstance had a very simple effect: it further delayed the development of the San Fernando Valley relative to surrounding regions of southern California, such as the nearby San Gabriel Valley, until water became available. This effectively occurred in 1913, when the Owens Valley Aqueduct was completed, making water for the general Los Angeles region plentiful. In order to gain access to this water the inhabitants of the San Fernando Valley annexed themselves to the City of Los

Angeles shortly thereafter. Note, however, that the Chatsworth Ridge Estates study area lies a short distance west of the limits of incorporated Los Angeles, signaling the fact that it was peripheral to these early historical developments.

As is usually the case, a small group of leading citizens recognized, in advance, the economic potential of the valley once water became widely available, and so laid plans for its development. A syndicate of 30 men, including notable figures such as Harry Chandler and Harrison Gray Otis, founded the Los Angeles Suburban Homes Company by purchasing the 47,500 acres Lankershim Ranch from the Los Angeles Farming and Milling Company in 1909. (This was effectively all the land the company retained after divesting 12,000 acres to Lankershim for his Lankershim Ranch, Land and Water Company development). Their price was \$2.5 million. They were led by H.J. Whitley, known as the "father of Hollywood", who served as general manager for the syndicate (*Los Angeles Daily Times*, September 24, 1909, page 1; Robinson 1961:37).

Whitley was responsible for the development of Hollywood in 1903, but even earlier had come to Los Angeles with a history of successful land development. Born in Canada, he started his American career as a professional townsite developer for the Rock Island and Northern Pacific Railroad, and later created a series of successful banks in Oklahoma prior to his arrival in California (Jorgensen 1982:144). His involvement with (and the activities of) the other members of the Los Angeles Suburban Homes Company extended beyond the San Fernando Valley, however: shortly after starting the development of the valley they purchased the 270,000 acres Tejon Ranch from Truxtun Beale (son of General Edward F. Beale) for \$3 million, and were involved in a series of similar purchases at Dana Point, and in New Mexico and Baja California (Crowe 1957:118). Whitley's recognition of the development potential of the San Fernando Valley, however, apparently foreshadowed even that of his fellow syndicate members. While developing Hollywood he had the foresight to recognize the importance of Cahuenga Pass as the primary access into the valley. As a result, Whitley purchased title to the Cahuenga Pass years before the syndicate was established, thereby controlling commercial development in the "gateway to the valley".

The boundaries of the syndicate's valley purchase started at the western side of the Rancho Ex-Mission lands (i.e., Encino) and ran eastward to Lankershim's development (at Whitsett Ave.); north to Roscoe Blvd; and south to the crest of the Santa Monica Mountains. According to a period account, the property was 15 miles long and 6.5 wide (*Los Angeles Daily*

Times, September 24, 1909, page 1). The map for this subdivision was filed on March 14, 1911, and it was designated "Tract 1000", the largest subdivision in Los Angeles County history. The principles in the syndicate reserved certain portions of the tract for their personal development and/or use, with their personal parcels ranging up to 1000 acres in size. Whitley and Chandler both took only 500 acres each, located near the corner of modern Van Nuys Blvd. and Sherman Way. Whitley built his own mansion on this land, a three-story Italianate home, which faced modern Van Nuys Blvd. and was located just south of the town center of Van Nuys. In later years it served as the Praisewater Funeral Home (Jorgensen 1982:150).

Three town sites were laid out by Whitley: Van Nuys; Marian (now Reseda); and Owensmouth (Chatsworth), due south of the study area. Critical to the development of these, beyond water, was transportation or, more precisely, accessibility. This appeared in a series of forms. First, the SPRR constructed an east - west rail line across the valley in the late 1890s. Known as the Chatsworth Park Branch, it was part of the effort to create a coastal route through Simi Valley, Ventura and ultimately Santa Barbara before heading north (cf. Cameron 1963). One outcome of this line is that it made the townsite of Owensmouth, in the northwest corner of the valley, easily reached, but it also opened-up all of Whitley's development area. The Chatsworth Park Branch followed a route west from Lankershim essentially along what is now Chandler Blvd., heading northwest in the vicinity of Coldwater Canyon to skirt the modern location of L.A. Valley College, and then due west following a route that runs parallel to and a short distance north of modern Oxnard Blvd. This is one of the alternative routes for the current proposed project, and still constitutes a rail right-of-way.

The second improvement in transportation was the construction of an all-weather east - west roadway, making the valley accessible to cars, horses and wagons and, ultimately, the electric trolley. Whitley was responsible for the construction of such a thoroughfare, then known as Sherman Way, which comprised the first real road in the valley beyond the existing north - south route (Lankershim Blvd.) which ran from Cahuenga Pass to San Fernando. Sherman Way was constructed in 1911 (Jorgensen 1982:122).

A period account, published in *Sunset Magazine* in 1914, describes Whitley's Sherman Way in glowing (if not florid) terms, pointing to the fact that it represented a state-of-the-art transportation area and required an almost unheard of investment for that time. As this early author notes:

[Whitley] made it two hundred feet wide, with the trolley in the center

and a drive way on either side. He laid an oil macadam pavement for general traffic and an asphalt concrete pavement for exclusive automobile traffic, built concrete curbs for sixteen miles of the twenty-two...He laid out a strip of parking along the trolley tracks, other fifty-foot strips of parking on either side. Then he proceeded to embellish the highway. First he planted rosebushes five feet apart, four rows of them on the main boulevard, two rows on the connecting links, fifty miles of roses in all. Not the ordinary hedge variety but blooded stock...Behind the roses he planted rows of exotic shrubs, oleanders red and white...Behind the bushes he set out rows of magnolias from the south, of flowering acacias from Australia, alternating with stately fan-palms from the Canaries. Next he jumped to India, to the shoulders of the Himalayas, planting a double row of the deodars made famous by Rudyard Kipling. Behind the silvery gray foliage of the deodars he found room for more ornamental shrubs, and at the outer edges of the broad parkings he provided somber Monterey pines as a fitting background. Then he rested.

If there is, anywhere, a highway that exceeds Whitley's twenty-two mile boulevard in width, length and in variety and character of its arboreal ornamentation, it has succeeded effectively in hiding its light under a bushel basket.

(Woehlke 1982 [1914]:125)

Further enhancing the effect of this broad highway, Whitley lighted its entire length with "ornamental electroliers", putatively costing \$100,000 alone to install. Having established such a standard of elegance for the boulevard, no "pioneer shacks" were allowed to be built anywhere in its vicinity (ibid). And with the initiation of the Pacific Electric Company's "red car" service, running 16 trains a day from Van Nuys to Hill St. down the middle of Sherman Way, the San Fernando Valley was finally opened for residential development.

The route of this twenty-two mile grand boulevard ran from Lankershim west along what is now known as Chandler Blvd. to Van Nuys Blvd. There it headed north to modern Sherman Way, where it again proceeded west, thereby connecting the town sites of Van Nuys, Reseda and Chatsworth with Lankershim. The original design of this roadway is still evident in the divided roadbed found in Chandler and Van Nuys Blvds. and Sherman Way, as well as the retained name of Sherman Way itself. The eastern segment of one alternative route for the current project follows the route of Whitley's boulevard from Lankershim west along Chandler approximately to Coldwater Canyon.

The combination of available water and accessibility finally even if belatedly opened up the San Fernando Valley for occupation. According to the 1910 census the valley had only about 3300 occupants; 65% of these were living in the older and more established town of San Fernando; about 26% resided in Lankershim; and the remaining 9% were residents of Chatsworth. But by 1940 population had exceeded 200,000 (Jorgensen 1982:90, 153), resulting in an average growth rate of almost 7,000 new inhabitants per year during this 30 year period. Much of this growth was precisely in those portions of the valley developed by Whitley.

Van Nuys was the focus of this initial spurt of growth, as it was the first project initiated by the syndicate. Town lots in Van Nuys were put on the market in 1911, while the open areas between this townsite and Reseda and Chatsworth were sold as small ranches and farms. These, in fact, were the primary emphasis of the development, which was marketed as a rare opportunity to obtain farming land within close proximity to Los Angeles. A period account (*Los Angeles Daily Times*, September 24, 1909, page 1) reporting the initial sale of the Lankershim Ranch to the syndicate, for example, made the following announcement:

CHANCE FOR SMALL RANCHERS

In the last two or three years lands of similar nature in this section of the State have been bringing prices so high as to oblige persons seeking acreage to go up into the fertile San Joaquin or Imperials Valleys...Within a very short time, according to the plans of the new developers, opportunity will be afforded for thousands to obtain at a fair price such lands as they desire, close to Los Angeles - so close that a trolley car could take the run in from thirty-five to forty minutes, the time dependent on the portion of the big tract set upon...The soil is uniformly rich and deep and of an alluvial character. It is declared to be of the best in Southern California for alfalfa, small fruits, and diversified farming. It is the largest single body of fertile, level land in this part of the State, and said to be the largest single body of land lying so near a big city, in the United States.

Chicken ranches were particularly common during this period, with the valley referred to as the "Petaluma of the South", in reference to this northern California town's large poultry industry (Jorgensen 1982:151).

The valley retained its primarily rural flavor through the Depression, serving as a region of small farms and fruit orchards (Robinson 1961:41). The Depression and subsequently World War II then further delayed the

development of the valley. It was not until after the war that the San Fernando Valley was fully transformed into the large area of suburbs that it is today.

Although the early creation of Van Nuys, Reseda and Chatsworth resulted in a series of nodes of early development that were dispersed across the valley, in some respects the overall development of the valley still followed a south to north and east to west trajectory, with the northern and western sides being the last to fully suburbanize. The southern foothills of the Santa Susana Mountains, which include the Chatsworth Ridge Estates study area, is a good example of this fact with this current project area still undeveloped. Because of its location away from the open flats of the valley where all early development occurred, it thus fell outside of the area of historical development and significant use.

1.3 Previous Research and Site Descriptions

The Chatsworth Ridge Estates study area was intensively surveyed on two previous occasions. Initially, eight archaeological sites were recorded on it (Bissell and Becker 1990). Three of these sites were thought to be historical in nature. These are CA-LAN-1740H, -1741H and -1742H. The remaining five sites, designated CA-LAN-209, -649, -1743, -1744, and -1745, are all prehistoric. A subsequent survey (W&S Consultants 2000) resulted in the identification and recording of two additional prehistoric archaeological sites: CA-LAN-2826 (W&S-1) and CA-LAN-2827 (W&S-2.)

Preliminary assessments of these resources suggested that the seven prehistoric archaeological sites were all intact and had the potential to be significant. Two of the three previously recorded historical sites, CA-LAN-1741H and -1742H, were found to consist of the foundations of demolished structures that were associated with contemporary trash and debris. They appeared to be post-World War II in age. While they possibly may have met the minimum age requirement of 50 years for historical resources, as specified by CEQA, they were found to be entirely lacking in integrity and thus to have no significance from an architectural perspective. Moreover, they did not have any recognizable archaeological value. Based on these considerations, they were not considered significant or unique cultural resources. The last historical site, CA-LAN-1740H, on the other hand, is a sandstone and mortar bridge that was thought to be potentially significant

from historical, architectural and/or engineering perspectives.

Thus previous surveys and assessments of the Chatsworth Ridge estates study area identified eight cultural resources warranting evaluation. All but one of them are prehistoric archaeological sites.

The eight relevant sites considered during this Phase II test project, and the previous work on them, are described and summarized in the following discussion.

1.31 CA-LAN-209

CA-LAN-209 was first recorded in 1978 by R. L. Pence and was subsequently rerecorded in 1990 by Kenneth M. Becker of RMW Paleo Associates (Bissell and Becker 1990). At that time, the site was estimated to be approximately 400 by 300 meters in size, and was described as a large habitation locale (camp) with midden soils, three rock shelters and cupule petroglyphs on one large sandstone outcrop.

This site was originally recorded to the south of the study area. During the 1990 rerecording, however, the northern edge of CA-LAN-209 was argued to extend onto the southern end of the study area; specifically involving the three rockshelters and cupule covered outcrop, which were recorded as part of the site area. It was also noted that a large portion of the site had apparently been destroyed by the construction of Highway 118. Hence, only a portion of the site still exists, and a part of this may fall within the study area.

The portions of this site that are presumed to fall within the Chatsworth Ridge Estates study area were relocated and evaluated during the 2000 survey (W&S Consultants 2000). The precise location of the property line at this particular spot was not clear at that time and a only few yards variance one way or the other was recognized as potentially placing a portion of the site inside or outside of the study area.

Those portions of the site thought at that time to potentially fall within the study area consisted of three rockshelters and a boulder containing approximately 15 cupules and incised lines, all found within a small boulder field. Lithic debitage was noted within the rockshelters and intervening between them. A subsurface deposit was also thought to possibly be present in and around these shelters. These site components appeared to be intact

and potentially archaeologically significant.

1.32 CA-LAN-649

CA-LAN-649 was rerecorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site was estimated to measure approximately 240 by 80 meters and was identified as a large stone tool quarry/workshop containing numerous quartzite cores, flakes, hammerstones and scrapers. As recorded, the southwestern margin of CA-LAN-649 extended onto the study area.

The southwestern portion of this site was confirmed to extend into the study area in 2000, as indicated by surface lithic artifacts consisting mostly of quartzite flakes and cores. The function of the site as a quarry/workshop, based on the exploitation of locally available metavolcanic and especially quartzite cobbles, was also confirmed at that time. It appeared to be intact.

1.33 CA-LAN-1740H

CA-LAN-1740H was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site is an Euro-American solid fill bridge made of local sandstone blocks, mortar and concrete. It crosses Devil Canyon and is located within the southern portion of the Chatsworth Ridge Estates study area. Its age was unknown at the time of original recording.

Continued existence of the bridge was confirmed in 2000.

1.34 CA-LAN-1743

CA-LAN-1743 was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site measures approximately 10 by 10 meters and was identified as a small, sparse lithic scatter consisting of four cultural items. CA-LAN-1743 is located within the southern portion of the study area. It was relocated in 2000, but it was unclear whether there were still extant archaeological resources at the site location.

1.35 CA-LAN-1744

CA-LAN-1744 was recorded in 1990 by Kenneth M. Becker of RMW Paleo

Associates. The site was estimated to measure approximately 30 by 5 meters and thought to be another small, sparse lithic scatter, in this case consisting of only three cultural items. CA-LAN-1744 is located within the central portion of the subject property. The groundsurface at this site was found to be intact when relocated during the 2000 survey.

1.36 CA-LAN-1745

CA-LAN-1745 was recorded in 1990 by Kenneth M. Becker of RMW Paleo Associates. The site was estimated as measuring approximately 15 by 10 meters and was identified as a third small, sparse lithic scatter, with a surface assemblage thought to comprise about 15 cultural specimens. CA-LAN-1745 is located within the central portion of the Chatsworth Ridge Estates. This site was relocated and found to be largely intact in 2000.

1.37 CA-LAN-2826

This site (originally given the temporary designation of W&S-1) was recorded on 2 May, 2000, by Joseph M. Simon of W & S Consultants. It was estimated to measure approximately 150 by 75 meters and to be a large stone tool quarry/workshop that contains a low density scatter of quartzite and volcanic cores, flakes, hammerstones and scrapers. It is located within the northern portion of the subject property. It appeared to be intact.

1.37 CA-LAN-2827

The second site (originally given the temporary designation of W&S-2) discovered on the Chatsworth Ridge Estates study area was also recorded on 2 May, 2000. The site was estimated to measure about 60 by 30 meters and consists of a small stone tool quarry/workshop that contains a very low density scatter of quartzite flakes. It too is located within the northern portion of the subject property. It is intact.

CHAPTER 2 FIELD METHODS

2.1 Introduction

Phase II archaeological fieldwork in the Chatsworth Ridge Estates study area was intended to establish the nature and significance of the eight sites, and to thereby provide baseline data from which determinations of the ultimate disposition of these cultural resources could be made. For the seven prehistoric sites this required the collection of a representative sample of artifacts and archaeological indicators, the establishment of the vertical and horizontal boundary of the cultural deposits, and an analysis of the recovered artifact assemblages from the prehistoric localities. For the historical site, CA-LAN-1740H, a bridge, it required an assessment of condition and integrity.

Procedures followed in the collection of data useful for establishing the nature and significance of the prehistoric sites included mapping, surface collecting of artifacts lying on the ground surface, and test excavation of pits to establish the presence or absence of a subsurface archaeological deposit, as well as to characterize such a deposit if found to be present on the site. We discuss each of these field methods below, concluding with a brief description of our fieldwork at the historical site.

2.2 Surface Collection

In order to determine the maximum areal extent of the sites lying within the study area, the initial field procedure at the site was to locate, map and collect all surface remains present on the ground surface. In order to locate all such remains, the general area of each site was walked by crewmembers spaced in approximate two meter intervals. Identified artifacts and archaeological indicators were then marked with flagging tape. Remains found within an area of approximately 3 meters square in size (i.e., within a circle with a one meter radius) were to be treated as discrete artifact associations and collected as clusters (however, no such concentrations were found on the site). Transit, stadia and surveyor's chain were subsequently used to map all remains or clusters of remains, which were numbered and collected by these provenience points.

2.3 Test Excavations

Test pits or auger holes were excavated on the sites in order to establish whether a subsurface deposit was present at each locale and, if present, to assess its significance and extent. Each test pit was dug with pick, shovel and trowel in arbitrary ten centimeter spits or levels. Spoils from each of these levels was dry screened through 1/8th inch mesh. All artifacts and archaeological indicators were collected and bagged by unit level. Excavation was continued through two culturally sterile levels (i.e., 20 centimeters), or until decomposing bedrock was encountered.

Auger holes were hand excavated with a 6 inch clamshell bit. These holes were dug in approximate 20 cm levels, with spoils also screened through 1/8th inch mesh.

The intensity of test excavation on each site varied as a function of presumed site size, probability of subsurface deposit, and other observable field conditions, including the presence of exposed bedrock and density of surface remains. In addition, test excavations at two sites, CA-LAN-209 and -649, was intended to determine whether the subsurface deposits at either site extended into the study area. That is, in both cases these are sites that are primarily located outside of the study area. The intention in these cases was determine whether parts of these sites fell within the Chatsworth Ridge Estates area, not to test them in a complete sense.

The amount of test excavation per site is detailed below:

CA-LAN-209 - 4 1X1m pits
CA-LAN-649 - 6 auger holes
CA-LAN-1743 - 2 1X1m pits
CA-LAN-1744 - 2 1X1m pits
CA-LAN-1745 - 3 1X1m pits
CA-LAN-2826 - 6 1X1m pits
CA-LAN-2827 - 2 1X1m pits

2.4 Historical Documentation

Fieldwork at site CA-LAN-1740H, a putative historical bridge, in contrast, was directed towards field documentation through photography, mapping and analysis to determine whether this feature maintained integrity. This was

combined with a previous study of historical aerial photographs and topographical maps (Geosoils 1999), which provides the only extant documentation of the history of this architectural feature.

CHAPTER 3 FIELD RESULTS

3.1 Introduction

In the next chapter we discuss the recovered archaeological remains from the Chatsworth Ridge Estates sites, including a summary of the laboratory procedures by which the collection was processed and analyzed, and a review of each site's assemblage in typological terms. However, prior to considering the artifact collections specifically, below we present a summary of the field results at each site in a more general sense, particularly with reference to the size of the surface manifestation of the sites, the presence/absence of subsurface remains, the nature of the soils, and what these features imply about these sites. As we shall see, only certain of the recorded site locations contained extant archaeological remains.

3.2 CA-LAN-209

This site was originally recorded to the southeast of the southernmost boundary of the study area; in 1990 the site area was extended into the property boundaries, into an area where a paved road crosses through a series of boulder piles and rockshelters. (Note that this is roughly 100 meters west of the originally recorded site area.) We placed four 1x1 meter test pits within the study area to determine whether CA-LAN-209 extends onto the property (Figure 2) and, if so, to evaluate this component of the site.

Unit #1 was placed two meters west of the paved road. It was excavated to decomposing sandstone bedrock, encountered at 20 cm depth. Soils were a very dark grayish brown (Munsell 10 YR 3/2) silty loam, and were heavily disturbed. One piece of lithic debitage was recovered at 10-20 cm, but this was mixed with an even greater quantity of modern glass fragments.

Unit #2 was located one meter west of the paved road. Soil conditions were identical to those in the previous pit and were, likewise, heavily disturbed. No archaeological remains were encountered.

Unit #3, also placed west of the road, was similar to the first two units. No archaeological remains were encountered.

Unit #4 was placed east of the paved road, just inside the property boundary.

Soils were similar to those found on the other side of the paved road but decomposing sandstone bedrock was 30 cm deep at this location. This unit was culturally sterile.

Surface collection in this portion of the site failed to result in the identification or recovery of any artifacts or archaeological specimens.

In summary, this portion of site CA-LAN-209 was found to be very heavily disturbed. A road is graded through it, removing the large majority of what was once the only flat ground at this location, and we found the few areas of extant soils to contain significant quantities of modern glass at all depths. Only a single archaeological indicator was recovered during the test excavation, a waste flake. This area therefore probably once constituted a very peripheral portion of CA-LAN-209. The Chatsworth Ridge Estates portion of this site, however, clearly no longer maintains integrity or significance.

3.3 CA-LAN-649

This site was originally recorded as primarily located in a small saddle and knoll immediately to the east of the study area, but extending just into the Chatsworth Ridge Estates property. This comprises a zone of relatively steep slope, making it extremely unlikely that a subsurface deposit would be present.

Six 6" auger holes were excavated within the study area and putative site boundary (Figure 3). Soils were found to be uniformly thin, rocky colluvium, dark yellowish brown (Munsell 10 YR 4/4) in color, varying from about 5 to 30 cm in depth. No archaeological remains of any kind were found.

Surface collecting also failed to result in the identification or recovery of any archaeological remains. Based on these findings, it is apparent that site CA-LAN-649 does not extend into the Chatsworth Ridge Estates study area.

3.4 CA-LAN-1740H

Fieldwork at this site, a historical bridge and dam, was directed towards documenting and assessing the integrity of this structure. A history of the study area, based primarily on an analysis of historical aerial photographs and topographical maps, was completed by Geosoils (1999). This provides the primary existing documentation of the history of this dam and thus can

be used in conjunction with the field data to assess the significance of this historical structure.

Based on the map and air photo reconstruction, this bridge and dam were constructed in approximately 1928 and appear to have been part of an early effort to subdivide the property for vacation lots. The study area was referred to as "Twin Lake Park" at that time, with the bridge forming part of the access road network that was fully graded, by 1929, for this subdivision. The dam, furthermore, served to create the upper of the twin lakes on Devil Canyon Creek. The road from the bridge onto the central portions of study area was dirt at that time (Geosoils 1999).

By 1930, approximately 18 residences were present in the general area; however, the lakes were even by that early date apparently drying up, with only a small amount of water visible in the air photos. By 1945 most of the graded roads had become overgrown with natural vegetation, indicating that the majority of the lots had never been sold, and no real population ever moved onto the study area property, per se. In late 1970 a fire destroyed all of the residences, with one exception, which is still standing and was heavily remodeled in the late 1970s.

CA-LAN-1740H, then, is a dam and bridge that were constructed circa 1928 to provide access to and to create a dam and lake for a small residential/vacation development. Little effort appears to have been made towards maintaining the lake that this structure was intended to create, perhaps due to the fact that the development was never particularly successful. Despite the fact that this lake is shown on a series of topographical maps (including the 1969 USGS Oat Mountain quad), the air photos indicate that the dam was largely ineffective in creating a lake of any permanence. However, the bridge across the dam top has served to provide access across Devil Canyon to the scattering of houses that are present in this general area.

The dam and bridge were found to consist of a solid structure that is 75 feet long, 12 feet wide and 36 feet high above the canyon bottom at its downstream (eastern) face. Examination of it reveals that it has experienced multiple episodes of repair and modification in order to keep it in operation as a dam and, primarily, single lane bridge (Figures 4 - 8). The downstream face shows a minimum of five and perhaps six episodes of construction and repair. The foundation of the dam, sitting on top of exposed bedrock in the canyon bottom, is mortared brick (Figure 5). The bridge may therefore have originally been an all brick structure crossing the canyon. This brick,

however, is currently overlain with random courses of large but unmodified boulders that rise up, in some areas, to the current road bed. In the middle of the span, above what is presumably the original spill gate, a wash-out at some point apparently removed the central portion of this boulder construction. This was replaced by courses of newer but much smaller unmodified field cobbles, mortared with a different cement (Figure 6). Above this solid dam structure, the road consists of a poured concrete bed. This too has experienced at least one episode of repair, the last of which appears to have resulted in the construction of a new wing dam and spill on the southern side of the canyon (Figure 7). This appears to be relatively recent, perhaps less than 30 years old.

Some of these repairs are also evident on the upstream (west) face of the structure. This is concrete faced, and at least two (and probably three) distinct poured facings are apparent (Figure 8). In addition, two episodes of wing dam construction can also be observed, the second of which is the one evident from the other bridge face.

It is then apparent that, in its roughly 70 year life span, this structure has experienced a regular cycle of storm damage and then repairs to keep the road in use; repairs which called upon whatever constructional resources were available at that moment. As a result, it is our opinion that, from the perspective solely of cultural resources issues and concerns, this heavily and repeatedly modified bridge and dam no longer maintains architectural or engineering integrity, and is therefore not a significant cultural resource. Note that this is not a comment on the engineering integrity of this structure from the perspective of safety, construction code, or usability (which we are not qualified to assess) but, instead, solely an evaluation of its integrity as a historical resource.

3.5 CA-LAN-1743

Two pits were placed on this small site (Figure 9). It was found to have been graded down to sandstone bedrock with only a small remnant -- about 3 cm - - of soil left on the ground surface. This soil was silty loam that was dark yellowish brown (Munsell 10 YR 4/4) in color. Both of the test pits were, accordingly, culturally sterile. Similarly, surface collection failed to result in the identification or recovery of any archaeological remains.

Site CA-LAN-1743 either was never an archaeological site, or was destroyed sometime subsequent to its original recording in 1990. In either case, there

are no extant cultural resources at this location.

3.6 CA-LAN-1744

Site CA-LAN-1744 was found to lie within an area of very shallow topsoil; in fact, essentially in an area where bedrock was exposed at the ground surface. The two pits excavated at this location (Figure 10) encountered decomposing sandstone bedrock at about 2-3 cm. The small amount of topsoil present consisted of silty loam that was dark yellowish brown (Munsell 10 YR 4/4) in color. No archaeological remains were encountered.

Surface collecting also failed to result in the identification or recovery of archaeological remains at this location.

There are no extant archaeological remains at the location of CA-LAN-1744.

3.7 CA-LAN-1745

Three 1x1 m pits were excavated at this large but low density archaeological site (Figure 11). Soils at this location proved to be an oxidized silt that is dark yellowish brown (Munsell 10 YR 4/4) in color. These thin soils overlay decomposing sandstone bedrock, which was encountered between 2 and 5 cm in depth.

Three archaeological specimens were recovered at this site. One of these was found during surface collection, per se; the other two were found in the 0-10 cm level of Unit #1. Given that this unit only went 2 cm deep, it is clear that these examples too are effectively surface remains that had gotten slightly intruded into or covered by soil.

The archaeological evidence at CA-LAN-1745 demonstrates that this is a small, low density surface lithic scatter, measuring only about 40 feet (12 m) in diameter. No additional archaeological remains are still present at this site location.

3.8 CA-LAN-2826

Six 1x1m test pits were excavated at this site, which is located on the open slopes towards the northern side of the property (Figure 12). Soils in these

units were in some respects similar to those found at the other sites within the study area; specifically, they were quite thin, with decomposing bedrock a short distance below ground surface. However, these soils consist of a residual oxidized B horizon that is dark yellowish brown (Munsell 10 YR 4/4) in color. Depth of decomposing bedrock was approximately 10 cm in all six units.

No subsurface deposit was found at this site. Surface collecting resulted in the identification and recovery of six prehistoric tools; another eight specimens were found on the ground surface of the test pits during excavation. The overall distribution of these finds falls within a 200 feet (62 m) diameter area, or about 3000 meters square.

CA-LAN-2826, in other words, is a relatively small and low density surface lithic scatter, with approximately one specimen per 215 meters square. All of these artifacts that were once present on it have now been collected.

3.9 CA-LAN-2827

Two 1x1m test pits were excavated on this small site (Figure 13). Soils and field conditions were fully equivalent to those encountered at CA-LAN-2826, reflecting the fact that both sites are located on similar slope positions towards the northern side of the property. Soil at CA-LAN-2827, in other words, was likewise a residual oxidized B horizon that was dark yellowish brown (Munsell 10 YR 4/4) in color. Decomposing bedrock was also encountered about 10 cm below ground surface in both pits.

No subsurface artifacts were found at this site. Two specimens were, however, recovered during surface collection. These were found in an area approximately 20 feet (6m) in diameter.

CA-LAN-2827 is clearly a very small, sparse lithic scatter. No additional artifacts are still present at this location.

CHAPTER 4 ARTIFACT ASSEMBLAGE AND ANALYTICAL CONCERNS

4.1 Introduction

Although the general patterns of artifact distribution, enumerated in the previous chapter, provide important information relative to the size and nature of the sites in the Chatsworth Ridge Estates study area, proper determination of the significance and scientific importance of these sites requires a more intensive analysis of the recovered artifact assemblages. Accordingly, in this chapter we consider these assemblages in analytical detail. We begin by detailing the laboratory procedures followed in the processing and curation of the recovered remains. Subsequently we outline the taxonomic system employed to categorize and classify the site collections. This is followed by a typological summary of the artifacts and archaeological indicators recovered from each the sites. Note, in this regard, that recovered artifact collections were limited to four of the eight sites: CA-LAN-209, -1745, -2826 and -2827.

4.2 Laboratory Procedures

Following the completion of the Phase II fieldwork at the Chatsworth Ridge Estates study area sites, the recovered artifact assemblages were taken to the W & S Consultants' laboratory for washing, processing and analysis. After each specimen was washed and labeled, metrical and typological analyses were performed. We provide measurements and weights for the various artifacts and archaeological indicators in the site catalogs (Tables 1, 3, 5 and 9) included in this report. In order to facilitate typological comparisons between this site and other similar sites from this same region, we have employed a standardized taxonomic system. We start by describing this classificatory system in some detail below.

4.21 Taxonomic Considerations

In considering the artifacts recovered from the the Chatsworth Ridge Estates study area sites, we employ a morphological stone tool typology first published by Whitley et al (1979) and now widely used in the region. This affords a number of advantages. First, because of its widespread use (e.g., Johnson 1979; W & S Consultants 1984, 1989a, 1989b) it permits easy

comparability between existing studies. Second, because it is morphologically rather than functionally based, it provides greater objectivity in taxonomic assignments. Specifically, it avoids the dangers inherent in inferring dubious functional purposes for stone tools that may have had multiple uses, and that often exhibit little in the way of formal attributes. In the Canaliño region, in particular, it is increasingly clear that most sites are characterized by expedient or casual tool assemblages, probably reflecting the fact that the sites resulted from dispersal phase activities that little emphasized formal patterns of behavior (W & S Consultants 1989b). Thus, a typology based on the elucidation of tool manufacturing stages, rather than one assuming final function of the implements, stands less chance of leading interpretations astray. However, this is not to imply that functional interpretations are unwarranted or undesired. Such is not the case; instead, it is simply to emphasize that functional interpretations must be made somewhat independent of - and therefore including other lines of evidence from - the typological assignments alone.

The morphological typology employed here is based on four major categories of stone artifacts (cf. Whitley et al 1979). These are: (i) groundstone implements; (ii) core/cobble tools; (iii) flaked stone tools; and (iv) tool manufacturing waste, or debitage. Groundstone implements are tools that have been pecked and/or ground into shape. They include manos (or mullers) and metates (or basal grinding slabs), along with mortars, pestles, stone bowls and comals (or griddles). Although there is a general association between groundstone artifacts and plant grinding, pulping and processing, as in the case of manos, metates, mortars and pestles, this is not invariably so: stone bowls and comals, for example, had other uses, with certain kinds of bowls, in particular, sometimes reserved for ceremonial purposes.

Groundstone artifacts are usually (but not invariably) made of softer lithic materials. Metates, for example, are often made from sandstone or some other sedimentary material; bowls and comals are typically manufactured from steatite (soapstone or talc schist). Manos, however, were often derived directly from river cobbles of appropriate size, so that quartzite is a common material source.

Core/cobble tools are generally large, bulky implements made by the re-use and/or modification of a river cobbles and lithic cores. They include 'hammerstones', 'choppers' and 'scraper planes'. Hammerstones are usually unshaped or minimally shaped, roughly fist sized, stones that exhibit characteristic battering and pounding scars, but often otherwise lack modification. Choppers are cobbles or cores that have been uniaxially or

bifacially flaked to create a relatively sharp edge. Scraper planes are high-backed, unifacially flaked tools that are usually 'biscuit-shaped' in plan, with edge angles near perpendicular, and with heavy use scars along their convex face.

All of these tools were apparently employed for heavy pounding, scraping and/or battering tasks. There is a frequent association of core/cobble tools with groundstone artifacts (specifically manos and metates) in the inland region (Whitley 1979b), suggesting that the two categories may have been functionally related; that is, that core/cobble tools may have served as part of a plant acquisition and processing toolkit. This is supported in reference to the scraper planes, in particular, which are argued to represent special yucca processing tools (Kowta 1969; Salls 1985). Further, this suggests in turn that the core/cobble tools were part of a woman's plant gathering toolkit (W & S Consultants 1989b).

Flaked or chipped stone tools are secondary reductions from cores and cobbles. That is, they represent tools manufactured from flakes struck the primary sources of lithic materials. These flakes may be used without modification as 'utilized flakes'; they may be bifacially flaked; or they may be unifacially flaked. It is apparent that the majority of the flaked or chipped stone tools in inland southern California are either utilized flakes with no modification, or have edges that have been flaked unifacially or bifacially, but exhibit little or no effort for further edge modification or shape regularization (W & S Consultants 1989b). Again, this further emphasizes the casual or expedient nature of these tools, and also implies that they may have been used for a variety of tasks with little functional specialization.

Correspondingly, the majority of the chipped stone tools from this region are what we have defined as biface or uniface 'edges', and they may have been used for any number of general cutting, scraping and abrading tasks. Of course, occasional projectile points and drills represent special types of bifaces with specific and known functions, whereas biface 'knives' (large leaf or knife shaped tools) are presumed to have been used for cutting and piercing/stabbing tasks.

Generally, chipped stone tools were made from material with particular flaking characteristics; specifically, those subject to conchoidal fracture. Crypto-crystallates such as chert and chalcedony, therefore, are common raw materials, but fused shale, quartzite, cherty-siltstone, rhyolite, andesite, basalt and occasionally obsidian may also be present in a collection. Because small hand specimens of rhyolite, andesite and basalt are, in fact, only

distinguishable with petrographic analysis, we treat them all as "fine-grained volcanics". And, as we have recently discovered (W & S Consultants 1991b), "fused sandstone", resulting from contact metamorphism between Miocene Conejo Volcanics and sedimentary beds, was also a lithic material of common use in the inland region. Because of its similarities to fused shale (based, of course, on similar metamorphic origins), it has often been mistaken for this latter material. This would be inconsequential, save for the assumption that the putative fused shale has its sole origins in Grimes and Happy Camp Canyons, north of Moorpark. Instead, it is apparent that a number of fused sandstone quarries are present in the inland region (particularly eastern Ventura County); that their respective lithic materials are widely misrecognized as fused shale; and that, therefore, lithic exploitation was probably much more widely ranging than the often inferred simple exploitation of major quarries at Grimes Canyon might suggest (W & S Consultants 1991b).

The final category of stone artifacts is what can be considered lithic waste or debitage. It includes spent cores, waste flakes, and angular shatter. There are a number of different kinds of cores and flakes, and the presence of these varieties at a site tends to signify different types of tool reduction or manufacturing techniques. For example, the presence of large numbers of secondary and tertiary flakes usually indicates that chipped stone tool manufacture occurred at a locale, whereas primary flakes alone might be associated with the making of the cruder chipped stone tools, or might be expected at quarries where only the preliminary stages of tool manufacturing were conducted. Similarly, relatively large proportions of tertiary flakes correlate with habitation/campsites, in that tool maintenance and finishing occurred at these locales. Furthermore, because different lithic materials tend to correlate with different categories of tools, the material present in the debitage collection can also be a clue to a site's function. Quartzite and other 'crude' lithic materials, for example, are often found where core/cobble tools are manufactured, whereas crypto-crystallates tend to occur where chipped stone tools are manufactured. And, in a general way, there is an association between these last materials, chipped stone artifacts, and habitation sites (W & S Consultants 1989c).

In addition to the lithic tool typology, other classes of artifacts may be present at inland southern California sites. Dietary remains, in the form of shellfish and faunal bones, are sometimes present, as are ornaments, usually in the form of shell beads. Where appropriate, based on the specifics of a recovered artifact assemblage, we consider these categories of remains below, as well.

4.3 Artifact Assemblage: CA-LAN-209

The artifact assemblage recovered from that portion of site CA-LAN-209 tested during this project is summarized in Tables 1 and 2. Table 1 is the catalog for the site; Table 2 provides details concerning lithic debitage.

As Table 1 shows, the large majority of the recovered remains found during the test excavation are shards of broken but modern glass. These have no archaeological value beyond the fact that they provide evidence of the degree of disturbance that the soils at this location have experienced. As this catalog makes clear, the soils in this area have been thoroughly mixed. The implication of this finding, in terms of archaeological remains, is that this area lacks integrity.

As seen in Tables 1 and 2, only a single archaeological specimen was recovered during the fieldwork at this site. This consists of a piece of lithic debitage or tool manufacturing waste. In this case this is a primary quartzite flake weighing 8.7 grams. Quartzite is a common and locally available lithic resource, with quartzite cobbles eroding out local conglomerates and gravels.

4.31 CA-LAN-209 Summary

The nature of the archaeological remains recovered from CA-LAN-209 are too limited to allow any assessment or even speculation concerning the nature of this site as a whole. However, the recovered assemblage is quite valuable for management purposes. It indicates that the study area is, at best, on the very periphery of this site. It further indicates that this portion of the study area is very highly disturbed. Any portion of CA-LAN-209 that once fell within the boundaries of the Chatsworth Ridge Estates property no longer maintains integrity, and is therefore not significant.

4.4 Artifact Assemblage: CA-LAN-1745

As in the previous site, the artifact assemblage recovered from CA-LAN-1745 was quite limited in both size and diversity. Tables 3 and 4 summarize the recovered remains from the site, which are limited to three specimens. All are pieces of lithic debitage or stone tool manufacturing waste.

Two of these specimens are quartzite. One of these is a primary flake; the second is a piece of angular shatter. The third specimen is metavolcanic. It too is a piece of angular shatter.

Quartzite and various types of metavolcanic (basalt, rhyolite, etc.) are common constituents of local gravels and conglomerates. The fact that two of the three specimens recovered at the site are angular shatter while the third is a primary flake suggests that this site is a minor location where the assaying of locally available materials occurred.

4.41 CA-LAN-1745 Summary

Judging from the recovered artifact assemblage, CA-LAN-1745 can be categorized as a very small and sparse lithic scatter. Most likely it was related to the assaying, directed towards the eventual quarrying, of locally available cobbles. Given the nature of the recovered assemblage, it is impossible to make any estimate of site age. Logically, however, this site was probably created when village sites in the nearby region may have been occupied. Fieldwork at the site has resulted in the collection of all archaeological specimens that were once present at this location.

4.5 Artifact Assemblage: CA-LAN-2826

A total of 14 worked artifacts and archaeological specimens were recovered from CA-LAN-2826 (Table 5). These include groundstone (Table 6) and core/cobble complex (Table 7) tools, as well as lithic debitage (Table 8).

The groundstone is limited to a single example. This is a Type 4C, shaped bifacial mano (see Whitley et al 1979). It is relatively small in size, circular in outline, and made of sandstone. It provides straightforward evidence for plant processing at the site.

The core/cobble complex tools, with five examples, are the most common worked artifact class at CA-LAN-2826 (Table 7). They include a Type 1 core scraper plane, made of cherty siltstone; two Type 3 core hammerstones, one andesite and the other quartzite; and one Type 1 cobble hammerstone that is also quartzite. Core/cobble complex tools were suited for heavy processing tasks and they are commonly found in association with groundstone. They appear to have been related to plant processing, possibly to the pulping and

extraction of plant foods such as roots, bulbs and tubers. Scraper planes specifically may have been used to pulp agave, a plant which is present on the site and the dry south facing slope where it sits.

Eight pieces of lithic debitage were also recovered from this site (Table 8). Locally available quartzite is the most common debitage material (5 specimens or 62.5% of the total), but quartz, chert and andesite are also represented, each contributing one specimen (12.5% apiece). Angular shatter is the most common debitage class, again at 62.5% of the total. Two (25%) of the debitage pieces are primary flakes; the last is a tertiary flake.

4.51 CA-LAN-2826 Summary

CA-LAN-2826 is by far the largest site in the study area, but it still qualifies as a small and low density surface lithic scatter. Although no chronological evidence was recovered from it, the function of this location is reasonably clear. It apparently served as a plant gathering and processing station, presumably oriented towards hard seeds, bulbs, roots and tubers (as opposed to acorns). As such, it was presumably ancillary to a large habitation site that would have been located somewhere in the general vicinity; in this case clearly outside of the Chatsworth Ridge Estates study area.

As is common at such sites, a small amount of lithic reduction also occurred at CA-LAN-2826. As in other instances on the property, this appears to have been oriented primarily towards the assaying of locally available cobbles, rather than towards intensive lithic quarrying, per se. In either case this was a casual as opposed to systematic activity, reflecting the general expedient nature of the tool kit.

As a result of the fieldwork at CA-LAN-2826, no additional archaeological remains are present on this site.

4.6 Artifact Assemblage: CA-LAN-2827

The final site with a recovered artifact assemblage is CA-LAN-2827 (Table 9). This assemblage was limited to two specimens. One of these is a Type 1 irregular (or multiplatform) core. It is quartzite. The second specimen is also quartzite. It is a primary flake.

These two specimens indicate that a very small amount of lithic reduction

occurred at this location. Again, this emphasized locally available quartzite.

4.51 CA-LAN-2827 Summary

The small artifact assemblage recovered from CA-LAN-2827 indicates that it is a sparse surface lithic scatter of unknown age, oriented towards a very minor amount of lithic reduction. As a result of the fieldwork at this site, there are no additional archaeological remains present at this location.

CHAPTER 5 CONCLUSIONS AND RECOMMENDATIONS

5.1 Summary

Test excavations and determinations of significance were conducted at eight archaeological sites in the Chatsworth Ridge Estates study area, Chatsworth, Los Angeles County, California. This Phase II fieldwork involved mapping, the surface collecting of groundsurface artifacts and archaeological indicators, and the hand excavation of test pits or augers on each site, along with laboratory processing, cataloging and analyses of the recovered artifact collections. Seven of these sites are prehistoric (aboriginal) in nature; the eighth is a dam and bridge dating to about 1928.

A number of the prehistoric sites were found to no longer be extant at the time of our fieldwork. Those that still contained archaeological remains were found, in each case, to comprise sparse surface lithic scatters; no subsurface deposits were found. Fieldwork at these surface lithic scatters resulted in the recovery of all extant artifacts and archaeological specimens at them.

In the following, we summarize the findings at each of these sites, as well as our final recommendations for their management and disposition.

5.2 CA-LAN-209

A small corner of site CA-LAN-209 was thought to potentially extend onto the southernmost edge of the Chatsworth Ridge Estates property. Testing resulted in the recovery of only a single waste flake, found in a very disturbed context. This indicates both that this portion of the study area is on the very periphery of this larger site, and that this peripheral area is entirely disturbed and lacks integrity. Development of the project therefore does not have the potential to result in direct adverse impacts to CA-LAN-209.

5.3 CA-LAN-649

A portion of a relatively steep slope on the eastern side of the Chatsworth Ridge Estates property abuts a portion of this archaeological site, which primarily is located outside of the study area. Fieldwork demonstrated that

this site does not extend into the project area. Development of the project therefore does not have the potential to result in direct adverse impacts to CA-LAN-649.

5.4 CA-LAN-1740H

This is a historical bridge and dam built circa 1928 as part of the original Twin Lake Park development. It apparently has been ineffective as a dam but, instead, has primarily served to provide access to the scattering of houses on the north side of Devil Canyon. Examination of the structure shows that it has been extensively altered over the years, through repairs presumably to fix storm damage, with as many as six major reconstructions having occurred. None of these repairs was faithful to the original construction materials or techniques, but instead employed whatever was at hand and convenient. The structure therefore lacks historical integrity and is accordingly determined not significant.

5.5 CA-LAN-1743

No archaeological remains of any kind could be identified at the location of this previously recorded site, which was found to have been bulldozed sometime after the site was first recorded in 1990. Development of the project therefore does not have the potential to result in adverse impacts to CA-LAN-1743.

5.6 CA-LAN-1744

As in the previous case, Phase II testing failed to result in the identification or recovery of archaeological specimens or artifacts of any kind at this site, and it is apparently no longer in existence. Development of the Chatsworth Ridge Estates therefore has no potential to result in adverse impacts to this cultural resource.

5.7 CA-LAN-1745

The artifact assemblage present at CA-LAN-1745 was found to consist solely of three pieces of lithic debitage. These indicate that this site served as a sparse surface lithic scatter. Phase II testing resulted in the recovery of all of

these specimens, thereby completely and adequately mitigating any potential for adverse impacts that might accrue to this site as a result of the development of the project.

5.8 CA-LAN-2826

Prehistoric archaeological site CA-LAN-2826 proved to be a sparse surface lithic scatter containing a total of 14 artifacts and archeological indicators. These indicate that it served as a prehistoric plant processing station. The Phase II fieldwork at this location resulted in the recovery of all extant artifacts at this location, thereby providing scientifically consequential information from and about it. This has served to completely and adequately mitigate any adverse impacts that this cultural resource might have the potential to suffer as a result of the development of the Chatsworth Ridge Estates project.

5.9 CA-LAN-2827

Archaeological remains at this site were limited to just two pieces of lithic debitage, demonstrating that this site is a very small and sparse surface lithic scatter oriented towards lithic quarrying. Both of these specimens have been collected. This has served to completely and adequately mitigate any adverse impacts that potentially could accrue at this location as a result of the proposed project. Development of the Chatsworth Ridge Estates project, therefore, does not have the potential to result in adverse impacts to this site.

5.10 Final Conclusions and Recommendations

Based on the current status of and the completed Phase II fieldwork on the archaeological sites within the Chatsworth Ridge Estates study area, it is apparent that the development of this project does not have the potential to result in adverse impacts to significant cultural resources. We therefore recommend no additional archaeological work for this property. However, following the suggestions of CEQA, we recommend that an archaeological monitor be present during topsoil grading in the areas of the previously recorded and examined archaeological sites.

RE: Addendum to Phase I Archaeological Survey of the Chatsworth Ridge Estates Study Area, Los Angeles County, California

Dear Hans:

Earlier this year, W&S Consultants conducted a Phase I archaeological survey of the Chatsworth Ridge Estates study area. At your request, we have completed a Phase I study of an immediately adjacent 13 acres parcel (Figure 1). This additional property is located on the western side of the previous study area, near its southwestern boundary. This letter provides a report on this addendum to the first study.

Methods

The phase I archaeological survey of the 13 acres parcel involved an archival records search at the California State University, Fullerton, Archaeological Information Center (AIC), and an intensive, on foot survey of the property. The archival records search is included as Attachment #1 to this addendum report.

The maps and records housed at the CSUF AIC indicate that the 13 acres study area had never been systematically surveyed by archaeologists. No archaeological sites had been recorded on it. However, as documented in our previous Phase I report for the project area, archaeological sites are known in the vicinity and, hence, this parcel was considered archaeologically sensitive.

Addendum/p. 2

The phase I survey consisted of an intensive and systematic examination of the property on foot. This involved walking the property in transects spaced approximately 20 meters apart, following the approach we had utilized on the adjacent property. The survey was conducted by David S. Whitley, Ph.D., and Joseph M. Simon.

Survey results and recommendations

The 13 acres parcel consists of a knolltop and slope and portions of the sides of Devil's Canyon. An abandoned dirt road and fire-break (across the knoll at the south) transect the property, most of which is covered with natural vegetation (chaparral and sage scrub, depending upon aspect).

No cultural resources of any kind were identified within this 13 acres parcel. Development of this parcel therefore does not have the potential to result in adverse impacts to cultural resources. However, in the unlikely event that such resources are identified during grading or construction, we recommend that an archaeologist be contacted to evaluate the remains.

Please call if there are any questions.

Sincerely,

David S. Whitley, Ph.D.
Principal

RE: Records Search for the Chatsworth Ridge Estates Project

Dear Mr. Simon,

As per your request received on December 6, we have conducted a records search for the above referenced project. This search includes a review of all recorded historic and prehistoric archaeological sites within a half-mile radius of the project area as well as a review of all known cultural resource reports. In addition, we have checked our file of historic maps, the National Register of Historic Places, the California State Historic Resources Inventory, the California Points of Historical Interest, and the listing of California Historical Landmarks in the region. The following is a discussion of our findings.

PREHISTORIC RESOURCES:

Twenty-seven prehistoric sites (see enclosed list) have been identified within a half-mile radius of the project area (see enclosed map).

HISTORIC RESOURCES:

No historic archaeological sites have been identified within a half-mile radius of the project area.

Inspection of our historic maps -- Santa Susana (1903, 1941) 15' series -- indicated that in 1903, there were some unimproved and improved roads, and few structures in place. Devil Creek, the Santa Susana Tunnel, the Southern Pacific Railroad, and the Santa Susana Pass were in place. In 1941, there was a loose network of unimproved and improved roads, and structures in place. Twin Lakes Park, Brandies Ranch, Iverson Ranch, Devil Canyon, Ybarra Canyon, Blind Canyon, the Santa Susana Pass, Stony Point, Highway 27, and Highway 118 were in place. Also, the Southern Pacific Railroad was in place.

The California State Historic Resources Inventory may list properties that have been evaluated for historical significance within a half-mile radius of the project area (see enclosed list).

The National Register of Historic Places lists no properties within a half-mile radius of the project area.

The California Historical Landmarks (1990) of the Office of Historic Preservation, California Department of Parks and Recreation, lists no landmarks within a half-mile radius of the project area.

The California Points of Historical Interest (1992), of the Office of Historic Preservation California Department of Parks and Recreation, lists no properties within a half-mile radius of the project area.

The listings of the City of Los Angeles Historic-Cultural Monuments indicated that there is one landmark within a half-mile radius of the project area.

No. 132 Stony Point Outcroppings
A natural site east of Topanga Canyon Blvd. considered one of the most picturesque areas in Los Angeles. Located in North Chatsworth. Declared: 11/20/74

PREVIOUS ARCHAEOLOGICAL INVESTIGATIONS:

Twenty-six studies have been conducted within a half-mile radius of the project area. There are nine additional investigations located on the Oat Mountain 7.5' USGS quadrangle and are potentially within a half-mile radius of the project area. These reports are not mapped due to insufficient locational information.

Please forward a copy of any reports resulting from this project to our office as soon as possible. Due to the sensitive nature of site location data, we ask that you do not include record search maps in your report. If you have any questions regarding the results presented herein, please feel free to contact our office at (714) 278-5395.

Invoices are mailed approximately two weeks after records searches are completed. This enables your firm to request further information under the same invoice number. Please reference the invoice number listed below when making inquiries. Requests made after invoicing will result in the preparation of a separate invoice with a \$15.00 handling fee.

Sincerely,

Esther Won
Staff Archaeologist

GEOTECHNICAL REPORT

November 6, 2001
Project No. 58-9194-02/003

Mr. Richard Garlinghouse
Presidio Chatsworth Partners, LLC
595 Market Street
San Francisco, California 94105

Subject: Response to County of Los Angeles Review Comments Dated October 23, 2001 and November 2, 2001, Chatsworth Ridge Estates Project, Tentative Tract No. 53138, Chatsworth Area, Los Angeles County, California.

References: Supplement to "Response to County of Los Angeles Review Comments", Dated October 9, 2001, by Kleinfelder, Inc., Chatsworth Ridge Estates Project, Tentative Tract No. 53138, Chatsworth Area, Los Angeles County, California, dated October 22, 2001, by Kleinfelder, Inc.

"Response to County of Los Angeles Review Comments Dated September 10 and 25, 2001, for Preliminary Geotechnical Investigation Report Dated August 8, 2001, Chatsworth Ridge Estates Project, Tentative Tract No. 53138, Chatsworth Area, Los Angeles County, California", dated October 9, 2001, by Kleinfelder, Inc.

"Preliminary Geotechnical Investigation, Chatsworth Ridge Estates Project, Tentative Tract 53138. Chatsworth Area, Los Angeles County, California", Project No. 58-9194-02/001, dated August 8, 2001, by Kleinfelder, Inc.

Dear Mr. Garlinghouse:

This letter presents our Response to Los Angeles County Department of Public Works Land Development Section Review Comments; dated October 23, 2001 and November 2, 2001 for the October 9 and 22, 2001 response submittals. The current review sheets were received via FAX by this office on November 5, 2001. As requested by the reviewer, copies of both the Geologic and Soils Engineering Review Sheets are attached to this response letter. The County's review comments are presented below in italics and are followed by our response to each comment.

GEOLOGIC REVIEW SHEET COMMENTS DATED 10/23/01 AND RESPONSES

Comment #1

Provide volume calculations for Qls-3 to verify the enlarged debris basin capacity on Lot 512 will accommodate the total amount of anticipated material from the landslide in addition to the design volume for debris control. Revise all related geologic and geotechnical cross-sections accordingly.

Response #1

The requested volume calculations by B&E Engineers are attached as requested. The calculations are based upon field verified and surveyed limits of the Q1s-3 area and estimated depths of slide debris, as indicated in our Supplemental to Response dated October 22, 2001. These calculations indicate that the basin has been sized by the design civil engineer to contain the debris from the slide in addition to the other drainage and debris requirements. Additionally, access is provided into the basin bottom area for maintenance and to remove any debris as necessary.

Comment #2

Comply with remarks/conditions on the attached Soils Engineering Review Sheet dated 11/02/01.

Response #2

Comment noted. Responses to the Soils Engineering Review Sheet dated 11/02/01 are provided in following section of this letter.

SOILS ENGINEERING REVIEW SHEET COMMENTS DATED 11/02/01, AND RESPONSES

Comment #1

The slope stability analysis (translational failure surface) for Cross Section U-U' yields a static factor of safety below County minimum standards. Recommend mitigation as necessary.

Response #1

The revised analysis for Cross Section U-U' indicating the County minimum calculated Factor of Safety (FOS) of 1.5 is attached. This revised analysis indicates that the proposed horse trail and development of the numbered lots have a FOS >1.5. Whereas the natural slope below the daylight cut has a calculated FOS <1.5. Hence, no mitigation is required.

Comment #2

The failure plane shown on Cross Section V-V' does not coincide with the information provided in the "Slope Stability Analysis Table" for the same cross section. Also, the calculated setback distance is not shown on Cross Section V-V' or the geotechnical map. Verify and make revisions as necessary.

Response #2

The information previously provided in the analysis for Cross Section V-V' for calculated factor of safety (FOS) of 1.586 was indicated as >1.5 in the Table and rounded up to 1.6 for depiction on Plate 21R of the October 22, 2001 submittal. Both the Table and Section (Plate 1) have been revised to indicate a FOS >1.5. Structural setbacks and restricted use areas are not required as the area having a FOS <1.5 is a natural slope below the proposed development, and will remain as a natural green space area, located outside the proposed development.

Comment #3

Provide volume calculations for Q1s-3 to verify the dimensions of the proposed debris basin. The basin must be designed to contain the total volume of the failed slide material in addition to the calculated drainage requirements.

Response #3

The requested volume calculations by B&E Engineers are attached as requested. The calculations are based upon field verified and surveyed limits of the Q1s-3 area and estimated depths of slide debris, as indicated in our Supplemental to Response dated October 22, 2001. These calculations indicate that the basin has been sized by the design civil engineer to contain the debris from the slide in addition to the other drainage and debris requirements. Additionally, access is provided into the basin bottom area for maintenance and to remove any debris as necessary.

Comment #4

Requirements of the Geology Section are attached.

Response #4

Comment noted. The Geology Section Review responses are provided in previous section of this letter.

Comment #5

Include a copy of this review sheet with your response.

Response #5

A copy of the review sheet is attached.

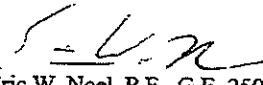

We trust that our Engineering Geologic and Soils Engineering responses are consistent with our previous (referenced) submittals. If you require any further information, please do not hesitate to contact either of the undersigned, at your convenience.

Respectfully submitted,

KLEINFELDER, INC.

MEMORANDUM

To: File -- 1R 53138 Job No: 99610-G

From: Ramy Awad

Date: November 5, 2001

Subject: Landslide Quantity / Debris Basin Capacity vicinity of lots 180 & 181

Limits and depth of above landslide area were determined on 10/16/01 in the field by our Geotechnical Consultant, Mr. Doug Cook of Kleinfelder and surveyed by B & E Engineers surveyor.

Based on above data, B & E Engineers generated a landslide bottom map and calculated the landslide volume to be 2,800 CY

Debris volume generated from the upstream drainage watershed area is estimated to be 1,081 CY based on the drainage concept of the project.

Total debris volume generated from upstream drainage area (1,081 CY) and potential landslide area (2,800 CY) for a total of 3,881 CY.

The basin is designed to have a capacity of 5,568 CY at elevation 1475, which provides 5' freeboard below building pads of lots 180 & 181.

It is estimated that all debris will be contained within the debris basin, below elevation 1472, and therefore, no impact from the debris on the offsite property owners

Debris Basin Capacity

PLAN SCALE: 1/8" = 1'-0" ELEV. REF. TO: 1.0

ELEVATION	DEPTH	LENGTH	VOLUME
1460	0	2	59
1462	1.00	2	252
1464	3.25	1	818.2
1465	3.80	5	3028.0
1470	5.42	2	1060
1472	8.10	3	1480
1475	10.80		

} Debris basin Capacity
bottom 1465 cone 1472 } 4088 CY
Top of basin 1475 with 5' free board
for a total capacity of 5568 CY

Lots 180 & 181
Elev. 1480

Basin Capacity to elev 1472 = 4088 CY
Basin Capacity to elev 1475 = 5568 CY

Landslide Debris Volume = 2800 CY
Drainage Debris Volume = 1081 CY
Total = 3881 CY

Therefore proposed debris basin will be adequate for all debris without affecting offsite properties

The Regional Planning Commission, developer and engineer are advised that:

PRIOR TO RECOMMENDING APPROVAL OF TENTATIVE TRACT OR MINOR LAND SUBDIVISION MAP:

1. Provide volume calculations for Q1s-3 to verify the enlarged debris basin capacity on Lot 512 will accommodate the total amount of anticipated material from the landslide in addition to the design volume for debris control. Revise all related geologic and geotechnical cross sections accordingly.
2. Comply with remarks/conditions on the attached Soils Engineering Review Sheet dated 11/2/01.

Previous review sheet dated 9/25/01

ACTION:

Tentative Map feasibility is not recommended for approval.

REMARKS:

1. The slope stability analysis (translational failure surface) for Cross Section U-U' yields a static factor of safety below County minimum standards. Recommend mitigation as necessary.
2. The failure plane shown on Cross Section V-V' does not coincide with the information provided in the "Slope Stability Analysis Summary Table" for the same cross section. Also, the calculated setback distance is not shown on Cross Section V-V' or the geotechnical map. Verify and make revisions as necessary.
3. Provide volume calculations for QIs-3 to verify the dimensions of the proposed debris basin. The basin must be designed to contain the total volume of failed slide material in addition to the calculated drainage requirements.
4. Requirements of the Geology Section are attached.
5. Include a copy of this review sheet with your response.

ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight (pcf)	Moist Sat. (pcf)	Cohesion Intercept (psf)	Friction, Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	4000.0	28.00	.000	.0	0

ANISOTROPIC STRENGTH PARAMETERS
specified for 1 Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	50.00	4000.0	28.00
2	60.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

500 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

Length of line segments for active and passive portions of sliding block is 55.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
---------	-------------	-------------	--------------	--------------	------------

1	1420.0	1135.0	1460.0	1180.0	60.0
2	1640.0	1385.0	1650.0	1385.0	45.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined
 are displayed below - the most critical first

Failure surface No. 1 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1365.91	1222.66
2	1400.93	1201.62
3	1448.07	1173.30
4	1640.51	1404.05
5	1652.85	1424.57

** Corrected JANBU FOS = 1.257 ** (Fo factor = 1.081)

Failure surface No. 2 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1361.17	1220.53
2	1399.99	1197.21
3	1447.13	1168.88
4	1645.74	1406.11
5	1657.38	1425.48

** Corrected JANBU FOS = 1.259 ** (Fo factor = 1.082)

Failure surface No. 3 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1378.00	1228.10
2	1411.31	1208.09
3	1458.45	1179.76
4	1640.63	1398.97
5	1656.44	1425.29

** Corrected JANBU FOS = 1.262 ** (Fo factor = 1.082)

Failure surface No. 4 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1368.06	1223.63
2	1406.43	1200.58
3	1453.58	1172.25

1	120.0	130.0	4000.0	28.00	.000	.0	0

ANISOTROPIC STRENGTH PARAMETERS
specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	f-value (degrees)
1	50.00	4000.0	28.00
2	60.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between $x = 1200.0$ ft
and $x = 1300.0$ ft

Each surface terminates between $x = 1350.0$ ft
and $x = 2200.0$ ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is $y = 1000.0$ ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

29.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees

Upper angular limit := (slope angle - 5.0) degrees

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)
*****
Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.
*****
```

 USER SELECTED option to maintain strength greater than zero

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 50)
*****
This warning is usually reported for cases where slices near the toe
of the slide mass have steep, negative base angles. Generally, this
error condition can be avoided by "raising" the lower angular limit
boundary to prevent generation of such deep failure surfaces.
*****

Project No. 58-9194-02/003

Mr. Richard Garlinghouse
Presidio Chatsworth Partners, LLC
595 Market Street
San Francisco, California 94105

Subject: Supplement to "Response to County of Los Angeles Review Comments", Dated October 9, 2001, by Kleinfelder, Inc., Chatsworth Ridge Estates Project, Tentative Tract No. 53138, Chatsworth Area, Los Angeles County, California

References: "Response to County of Los Angeles Review Comments Dated September 10 and 25, 2001, for Preliminary Geotechnical Investigation Report Dated August 8, 2001, Chatsworth Ridge Estates Project, Tentative Tract No. 53138, Chatsworth Area, Los Angeles County, California", dated October 9, 2001, by Kleinfelder, Inc.

"Preliminary Geotechnical Investigation, Chatsworth Ridge Estates Project, Tentative Tract 53138. Chatsworth Area, Los Angeles County, California", Project No. 58-9194-02/001, dated August 8, 2001, by Kleinfelder, Inc.

Dear Mr. Garlinghouse:

This letter presents our supplement to Kleinfelder, Inc. Response to Comments; dated October 9, 2001 to review comments made by the County of Los Angeles Department of Public Works Land Development Section. It is based upon discussions at the meeting held on October 9, 2001 at the County Offices between the reviewers and representatives of Kleinfelder, Inc. at which time the findings of our "Response" were verbally summarized.

The most recent revision of the 100-scale map for Tentative Tract 53138, dated October 19, 2001, by B&E Engineers is used as the map base for this supplemental submittal. Revisions made to the tract map since the October 3, 2001 map which was utilized as the map base for the referenced October 9, 2001 response include: reconfiguration of the limits for landslide Qls-3, relocation and enlargement of the debris basin located on Lot 512, revision of the grading on the proposed cut slope to avoid any grading of the landslide Qls-3 or previously recommended removal of the slide debris inclusive of offsite grading, and renumbering of the lots within the Tract above Lot 180 to accommodate the loss of one lot due to relocation of the basin on Lot 512.

The reconfiguration of landslide Qls-3 limits is based on a field survey of the area conducted on October 16, 2001 by B&E Engineers, Inc. and Kleinfelder, Inc. The new configuration of the Qls-3 area delineates six surficial slumps, each between two and five feet thick, and one larger slide mass that is estimated at ten feet thick.

The debris basin on Lot 512 was moved to the west to avoid grading at or near the toe of the landslide Qls-3 debris, and enlarged to accommodate 100% of the calculated volume of debris from the slide and adjacent slumps. A lot was lost as a result of the enlargement and relocation

of the basin. Therefore, all the single-family residential lots within the tract above lot number 180 have been reduced by one number to reflect this change.

The Site Plan and Geologic Maps (Plates 13R and 14R) along with the Geologic Cross Sections (Plates 15R, 16R and 18R) and Slope Stability Analysis Sections (Plates 19R, 20R and 21R), have been updated to reflect the changes in the grading as depicted on the revised map base and lot renumbering.

The slope stability analysis for Sections P-P' and Q-Q' has been revised to reflect the recently surveyed limits of the landslide Qls-3 area, and are attached to this submittal. The stability analysis for Section O-O' was evaluated for possible revision due to potential changes in grading of the slope and no significant changes that would affect the stability of the slope were found. Hence the prior analysis remains valid for Section O-O'.

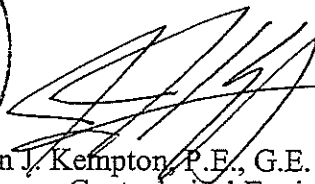

We trust that this supplement to our Engineering Geologic and Soils Engineering responses are consistent with discussions during our meetings of October 1 and 9, 2001, and that they fully document any outstanding issues required for approval of the Tentative Tract Map. If you require any further information, please do not hesitate to contact either of the undersigned, at your convenience.

Respectfully submitted,

KLEINFELDER, INC.

K. Douglas Cook, R.G., C.E.G. 1391
Senior Engineering Geologist

Analyses Number	File Name	Profile Name	Analyses Type	Condition	FS (Static)	FS (Pseudo-Static)	Description/Comments
1		A-A'	Parallel	South Slope Bridge Abutment	3.1	2.2	Existing condition stable, no improvements recommended
2		B-B'	Parallel	Southwest Slope Bridge Abutment	2.1	1.5	Existing condition stable, no improvements recommended
2		B-B'	Parallel	Southwest Slope Bridge Abutment (CDMG Tension crack)	2.3	1.6	Tension crack at the toe stability evaluation
3		C-C'	Qls Back Calc.	Existing landslide -Back Calculation of Slide Plane	1.0	N/A	Evaluation of existing conditions
3		C-C'	Parallel	Proposed Grades with Landslide Removed	1.0	<1.1	Evaluation of slope assuming failure of Qls-1 (removal of Slide Debris)
3		C-C'	Parallel	Proposed Grades with Landslide Removed	1.6	1.2	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed
3		C-C'	Parallel	Proposed Grades with Landslide In-Place	1.6	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
4		C2-D'	Parallel	Proposed Grades with Landslide Removed	<1.5	<1.1	Evaluation of existing conditions, FS<1.5; Slope mitigation (RUA) required
4		C2-D'	Parallel	Proposed Grades with Landslide Removed	1.7	1.3	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed (With Landslide In Place = Critical Case)
4		C2-D'	Parallel	Proposed Grades with Landslide In-Place	1.5	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
5		D-D'	Cross	South Facing Cut Slope 3	>1.5	>1.1	Stable by observation Cross Bedding no remediation required
6		D-D''	Parallel	Proposed Grades with Landslide Removed	<1.5	<1.1	Evaluation of existing conditions, FS<1.5; Slope mitigation (RUA) required
6		D-D''	Parallel	Proposed Grades with Landslide Removed	1.7	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed
6		D-D''	Parallel	Proposed Grades with Landslide In-Place	1.7	1.2	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
7		E-E'	Parallel	Daylight cut at top of slope	1.6	1.2	Block analysis of entire slope
7		E-E'	Parallel	Daylight cut at top of slope	1.9	1.4	Initiation at mid slope
7		E-E'	Parallel	Daylight cut at top of slope	2.5	1.5	Top of slope with 13 degree bedding plane analysis
8		F-F'	Cross	Daylight cut at top of slope	2.4	2.0	Circular Analyses with 5' tension crack
9		G-G'	Parallel	Daylight cut at top of slope/Qls-2	1.4	---	Evaluation of existing conditions, FS<1.5; Slope mitigation required
9		G-G'	Circular	Daylight cut shear key / Geogrid Reinforced Slope	1.5	1.1	Circular failure through geogrid slope (With Qls-2 Removed)
9		G-G'	Parallel	Daylight cut shear key / Geogrid Reinforced Slope	1.9	1.5	Along bedding failure at heel of reinforced shear key
10		H-H'	Cross	Fill Slope	>1.5	>1.1	Stable by observation and I-I' Analysis
11		I-I'	Cross	Fill Slope	1.7	1.2	Assumed rotational failure below B' Street
11		I-I'	Cross	Fill Slope	1.8	1.3	Assumed rotational failure above B' Street
12		J-J'	Cross	Fill over cut slope	>1.5	>1.1	Stable by observation, cross bedded slope
13		K-K'	Circular	Fill Slope	1.9	1.3	Bottom of fill slope
13		K-K'	Circular	Fill Slope	1.9	1.4	Middle of fill slope
13		K-K'	Circular	Fill Slope	2.0	1.4	Top of fill slope
13		L-L'	Parallel	Fill Slope	1.7	1.1	Sandstone Block Failure
14		L-L'	Cross	Fill over Natural Slope	1.8	1.5	Sandstone Circular failure
15		M-M'	Circular	Proposed Fill slope with Retaining Walls	<1.5	<1.1	Circular failure through engineered fill with retaining walls FS<1.5 and <1.1
15		M-M'	Circular	Proposed Fill slope with geogrid reinforcement	1.5	1.1	Circular failure through geogrid reinforced engineered fill
16		M2-M2'	Circular	Proposed Fill slope with geogrid reinforcement	2.3	>1.1	Block failure along backcut and bedding planes
17		N-N'	Syncline Parallel	Proposed Cut Slope	>1.5	>1.1	Stable by observation; Steeply dipping bedding

October 9, 2001

October 9, 2001
Project No. 58-9194-02/003

Mr. Richard Garlinghouse
Presidio Chatsworth Partners, LLC
595 Market Street
San Francisco, California 94105

Subject: Response to County of Los Angeles Review Comments Dated September 10 and 25, 2001, for Preliminary Geotechnical Investigation Report Dated August 8, 2001, Chatsworth Ridge Estates Project, Tentative Tract No. 53138 Chatsworth Area, Los Angeles County, California

Reference: "Preliminary Geotechnical Investigation, Chatsworth Ridge Estates Project, Tentative Tract 53138. Chatsworth Area, Los Angeles County, California", Project No. 58-9194-02/001, dated August 8, 2001, by Kleinfelder, Inc.

Dear Mr. Garlinghouse:

This letter presents our response to the review comments made by the County of Los Angeles Department of Public Works Land Development Section regarding our referenced Preliminary Geotechnical Investigation report. The comments are respectively contained in the Geologic Review Sheet dated September 10, 2001 by Mr. Greg K. Johnson, and the Soils Engineering Review Sheet, dated September 25, 2001 by Mr. Mark A. Steuer.

A meeting was held on October 1, 2001 with both of the county reviewers and the undersigned respondents to clarify the intent of each comment and present the scope of our responses. As requested, copies of both Review Sheets are attached to this response letter. The County's review comments are presented below in italics and are followed by our response to each comment.

GEOLOGIC REVIEW SHEET COMMENTS AND RESPONSES

Comment #1

Provide additional surface and/or subsurface investigation to more fully define the limits of the currently mapped landslides and depth to slide planes, particularly Qls-1. The extent of the proposed Restricted Use Areas associated with landslides Qls-1 and Qls-2 are highly dependent on the limits of these slides and their respective slide plane geometries therefore, further definition of the mapped slides, particularly Qls-1, is warranted. Projection of the Qls-1 rupture surface along bedding as shown on Cross Section C-C' suggests this landslide extends much further upslope than currently shown.

Response #1

Additional reconnaissance geologic mapping, topographic and air photo analysis has been conducted as requested. This additional work has slightly revised in an upslope direction the head scarp area location of Landslide Qls-1. As discussed at our meeting, subsurface exploration

of the slide and slope area would be very difficult due to access and environmental constraints of the hillside that is to remain as a natural slope (Natural Slope 4) within the proposed development. No development is proposed for the north facing dip slope in the immediate vicinity of, or above landslide Qls-1. Future headscarp failure of this slide may propagate up slope following the dip of the local geologic structure. The up dip daylight of which is near the hill crest that is also planned to remain as a natural slope area.

The stability analysis for Cross Section C-C' indicates that a Factor of Safety of 1.5 can not be calculated for the north facing Natural Slope #4, and that a structural set back and Restricted Use Area (RUA) is required. The depth of the failure model used for the calculated FS =1.5 was significantly deeper than the existing translational failure is modeled.

A south facing, Cut Slope #5 is proposed for the south facing slope over the ridge crest adjacent to Qls-1. Cut Slope #5 will be stable by inspection with respect to the southerly direction due to the into slope northern dip orientation of the geologic structure (bedding) of the Chatsworth Formation Sandstones. However the slope is not grossly stable with a calculated FS=1.5 due to the instability of the adjacent north facing Natural Slope 4 and Qls-1. As previously indicated, a RUA has been recommended which included the south facing slope as indicated on Plate 13R.

The stability analysis for Sections C-C', C2-D'' and D-D'' which were used to evaluate the recommended RUA are summarized in Table 1 (Revised) and are attached.

Comment #2

Prior to allowing any grading within Restricted Use Areas, the consultant must clearly demonstrate the following: a) any proposed grading will not worsen existing conditions; b) adjacent property will not be adversely affected; c) the area subject to instability and the Restricted Use Area must be contained on the same lot; and d) the change in use will not worsen existing conditions, e.g., change from natural area to development requiring irrigation.

Response #2

We understand that any recommended RUA's cannot coincide with proposed grading that may "worsen conditions" in that area or the adjacent parcel and that RUA's must be fully contained within the same lot. We have reviewed each RUA with B&E Engineers, to verify these conditions are met in the resubmitted Tentative Tract Map dated October 3, 2001. We also understand that RUA's cannot require special maintenance such as landscaping or irrigation.

Lots 54 and 55 have been reconfigured and is located outside the RUA for Qls-1. Cut Slope #5 located just north of Lot 55 remains within the RUA and is now to be include within one of the numbered open space lots.

The grading of the south facing Cut Slope #5 will not have any significant impact on the stability of the adjacent north facing slope and Qls-1. The grading will provide for drainage of surface waters which now flow uncontrolled over the surface and percolate into the subsurface. It is recommended that the graded surface of this cut slope not be landscaped or irrigated to help reduce the potential infiltration of surface water.

Comment #3

Extend Geologic Cross-Section D-D' northerly to the bottom of Devil Canyon and further evaluate the stability of proposed lots and streets considering a) daylighted bedding along apparent dip and b) loss of support due to failure of landslide Qls-1. Recommend revised

structural setbacks, restricted use areas and mitigation, if factors of safety do not meet County minimum standards.

Response #3

Cross Section D-D' was initially drawn to depict the south facing Cut Slope 3. However, Section D-D' has been extended northward to the bottom of Devil Canyon as requested to include portions of Natural Slope 4 and Landslide Qls-1. The extended cross section is shown in plan on Plates 13R and 14R, and in section on Plate 15R. Additional slope stability analyses have been calculated for this revised section with respect to Landslide Qls-1 and Natural Slope 4. The results of the additional slope stability analyses are shown on the attached Table 1 (Revised), Summary of Stability Analyses, and the calculations are attached to this letter. Based on the results of the analyses, the conditions a) daylighted bedding along apparent dip and b) loss of support due to failure of landslide Qls-1 calculated to have acceptable factors of for the proposed development located along the ridge top. Additional discussion regarding the shear strength parameters used in the analyses is provided in our response to comments from the Soil Engineering Review Sheet.

Comment #4

Discuss the ability of the geotextile-reinforced keyway, shown on Geologic Cross Section G-G', to support the proposed lots considering complete failure and lack of support from Qls-2. Was this situation evaluated in the stability analyses? It appears that failure of the unmitigated portion of Qls 2 will undermine the proposed mitigation. Recommend additional mitigation, structural setbacks and restricted use areas, if factors of safety do not meet County minimum standards.

Response #4

We previously evaluated the geotextile reinforced keyway in Section G-G'. Additional stability analyses was conducted assuming failure and lack of support of Qls-2 in Section G-G'. The results of the analyses are presented in Table 1 (Revised) and the calculations are attached. Based on the stability analyses, the slope is considered stable with a factor of safety of 1.5 for the Lots 27, 28, and 29 located above the daylight cut. .

Comment #5

Provide further evaluation of the stability of the existing topography, the proposed fill slope and the proposed retaining walls, shown on Geologic Cross Section M-M', considering a daylighted bedding condition along both true dip and apparent dip of bedding. Recommend mitigation, if factors of safety do not meet County minimum standards.

Response #5

Additional analyses was conducted on Section M-M' considering a daylighted bedding condition along true dip (Section M2-M2') and apparent dip of bedding as shown on Section M-M'. The results of the analyses are presented in Table 1 (Revised) and the calculations are attached. Based on the stability analyses, the proposed fill slope and retaining walls will require geotextile reinforcement. For preliminary design purposes we evaluated the required geotextile reinforcement embedment lengths, and type using the Miraslope V. 2.33 program. Based upon our analysis the minimum reinforcement needed to obtain the required calculated factor of safety consist of 16 layers of Mirafi 10 XT (or equivalent), 60 feet wide place at vertical intervals of 4 feet. The backcut will need to be laid back to a 2:1 (H:V) inclination. The analysis of the slope and cross sections are summarized on Table 1 (Revised) and the calculations are attached.

Comment #6

Identify the locations and provide the logs for all trenches excavated by the consultants for this investigation or provide an explanation for the omission of these trenches from the submitted report. Only 21 of the reported 31 test pits excavated are shown on Plates 13 and 14 or included in the trench logs in Appendix A.

Response #6

A total of 31 trench excavations were initially proposed. However due to plant and stream crossings (environmental) and other access constraints only 21 of the trenches were excavated for this study. Each of the 21 excavated trenches retained the respective location numbers as initially laid out. The logs of the excavated trenches were presented in Appendix B of our August 8, 2001 report. Test pit numbers that appear to have been skipped were not excavated.

Comment #7

Please provide Cross Section AA-AA' referred to in Appendix C of the report. Identify the location and orientation of this section on Plates 13 and/or 14.

Response #7

Section U-U' from the August 8, 2001 report is Section AA-AA' which was re lettered during drafting of the Plates, late in the preparation of the report. The analyses previously presented in Appendix C of the report has been updated to indicate that Section U-U' was formerly labeled as Section AA-AA'. The revised calculations are attached and the summary of the calculations are included in Table 1.

Comment #8

Recommend mitigation for all areas that do not meet County minimum standards for factors of safety. This includes, but may not be limited to, the pseudostatic analysis for block failure along Section K-K' and the pseudostatic analysis for circular failure with a buttress fill along Section Q-Q'.

Response #8

Our slope stability analysis conducted for the project slopes inclusive of Sections K-K' and Q-Q' have been updated. The additional analyses includes pseudostatic analyses of a block failure along Section K-K' and a pseudostatic analyses within the replacement fill in Section Q-Q'. The results of the analyses are presented in Table 1 (Revised) and the calculations are attached. For those conditions where the calculated factors of safety were less than the required minimums we have presented herein recommendations for mitigation.

Based on the results of the analyses, the mitigated slopes are considered to be stable with static and pseudostatic factors of safety of at least 1.5 and 1.1, respectively .

Comment #9

Provide static and pseudostatic analyses to evaluate the factors of safety of Natural Slope #2 below the daylight cut slope shown on Geologic Cross Section U-U'. Analyses should consider both failure along bedding and across bedding. Recommend mitigation, structural setbacks and restricted use areas if factors of safety do not meet County minimum standards.

Response #9

See Response to Comment No. 7. Section U-U' from the August 8, 2001 report is Section AA. The analyses previously presented in Appendix C of the report has been updated to indicate that Section U-U' was formerly labeled as Section AA-AA'.

Comment #10

Prepare a geologic cross section, similar to Cross Section U-U' from Browns Canyon through the landslide of Natural Slope #2 to the top of the slope extending to at least proposed "J" Street. Provide stability analyses to determine static and pseudostatic factors of safety for failure along bedding, across bedding and considering failure and lack of support of the landslide below the proposed horse trail, Lots 164-168 and "B" Street. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do meet County minimum standards.

Response #10

Section V-V' has been prepared through the surficial landslide area of Natural Slope #2 as requested. Additional slope stability analyses was conducted for both static and pseudostatic conditions and considering failure and lack of support of the landslide below the proposed horse trail, located adjacent to Lots 164-168 and "B" Street. The location of Section V-V' is shown on Plate 14R and the cross section is shown on Plate 18. The analysis of the existing natural slope indicate that the lower portions of the slope calculate to have a factor of safety below the requirements. However no development is proposed in this area and the slope is to remain in its current natural state.

Based on the results of our analyses, the lots located above the daylight cut of the natural slope is considered to be stable with required static and pseudostatic factors of safety. The results of the slope stability analyses are summarized in Table 1 (Revised) and the calculations are attached.

Comment #11

Prepare a geologic cross section oriented approximately north-south extending from "A" Street through boring KB-7 and Lot 486 down into and across the bottom of Devil Canyon. Provide stability analyses using appropriate shear strengths to determine static and pseudostatic factors of safety. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do not meet County minimum standards. The description of the rock slope in Appendix C indicates "the sandstone is generally very weak to weak rock."

Response #11

Section W-W' was prepared as requested. The location of the section is shown on Plates 13R and 14R, and the cross section is presented on Plate 18. Lot 486 is a nonstructural green belt / parksite lot located at the top of the existing natural slope that will not be included in the proposed grading of the development. Based on the results of our analyses, the lots located above the daylight cut of the natural slope is considered to be stable with required static and pseudostatic factors of safety. The results of the slope stability analyses are summarized in Table 1 (Revised) and the calculations are attached.

Comment #12

Provide an additional geologic cross section between Sections N-N' and U-U' through Natural Slope #1 and proposed Fill Slope #3. Orient the section in the most critical direction (approximately east west) and extend the section from the bottom of Browns Canyon through Lots 173-179 and across "B" Street. Perform stability analyses using appropriate shear strengths to determine the static and pseudostatic factors of safety. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do not meet County minimum standards.

Response #12

Section X-X' was prepared to evaluate Natural Slope #1 and Fill Slope #3 as requested. Additional slope stability analyses was also conducted. The location of the section is shown on Plate 14R and the geologic section is presented on Plate 18. The results of the analyses are summarized in Table 1 (Revised) and the calculations are attached. Based on the results of our analyses, the slope is considered to be stable with required static and pseudostatic factors of safety and no mitigation is recommended.

Comment #13

Based on the State of California Seismic Hazards Maps, at Oat Mountain Quadrangle, areas of the subject site are located in an area with a potential for liquefaction. Engineering geology and soils engineering reports must address the potential for liquefaction and ground failure with respect to the proposed bridges. Please refer to the attached Materials Engineering Division's "Interim Geology Review Guidelines for Ground Failure/Liquefaction" (GS045 Rev. 5/18/99). Provide this office with two (2) original copies of all reports for review and distribution to the State of California Division of Mines and Geology.

Response #13

As discussed in our August 8, 2001 report, we acknowledge that portions of the site are situated within areas designated by the State as having a potential for liquefaction. As discussed on Pages 13, 20, 32 and G-4 of the August 8, 2001 report, the areas of potential liquefaction are located in the stream channels adjacent to the proposed bridges. With the noted exceptions of the proposed bridges, the areas mapped as having a liquefaction potential are not considered to impact the proposed development. Accordingly, the liquefaction potential of the soils adjacent to the bridge foundations is to be addressed in the planned design level geotechnical reports for the proposed bridges. The proposed bridges will require design and construction of bridge piers that not only penetrate through these materials but recognize possible negative skin friction in the event of liquefaction. Drilling was not performed in these areas at this time due to environmental restrictions and access issues but we recognize that exploration will be required in these locations prior to approval of the final design of the bridges.

SOILS ENGINEERING REVIEW SHEET COMMENTS AND RESPONSES

Comment #1

Provide geotechnical update report/letter which specifically addresses and evaluates the latest tentative tract map submitted through the Department of Regional Planning..

Response #1

This response letter is based on the most recent revision of the map for Tentative Tract 53138, dated October 3, 2001, by B&E Engineers. Revisions made to the tract map since the date of the map utilized as basis for the referenced report include addition of a helicopter pad in the northeast corner of the site, and redesign of Lots 54 and 55, to exclude the recommended RUA and Cut Slope #5 as they have been incorporated into the adjacent green space lot.

We have also informed the project engineer that is imperative that we be notified of any submitted revised maps as they would need to be addressed in writing by Kleinfelder.

Comment #2

Provide a geotechnical map with corresponding cross sections which utilizes the current tentative map as a base.

Response #2

See Response to Soils Comment No. 1. The current map and geologic sections shown on Plates 13R, 14R, 15R, 16R and 18 are based on the most current revision of the Tentative Tract map dated October 3, 2001. Our stability analysis has been summarized in section on Plates 19, 20, and 21.

Comment #3

Clearly show the following on the geotechnical map and corresponding cross sections:

- a. Existing and proposed grades.*
- b. Lot lines.*
- c. Approximate limits and depth of removal and recompaction of slide debris and unsuitable soils.*
- d. Grading required for construction of buttress/stabilization fills, including areas of geotextile reinforcement.*
- e. Location of "Restricted Use Area(s)".*
- f. Mitigative measures, per the geotechnical engineer's recommendations.*

Response #3

We have provided to the County in this submittal, original prints and not duplicated copies of the plates. Plates 13R, 14R, 15R, 16R have been revised and Plate 18 added to clearly address the respective items identified in Comment No. 3.

Comment #4

Provide geotechnical cross sections AA-AA', CC-CC' and C3-C3' and identify their locations on the geotechnical map.

Response #4

With respect to Section AA-AA', see our Response to Geologic Review Sheet Comment No. 7. Sections CC-CC' and C3-C3' were originally used to evaluate and assess the limits of the restricted use area adjacent to Natural Slope 4 and Qls-1. Sections CC-CC' and C3-C3' have been replaced in this submittal with sections C-C', C2-D", and D-D". The locations of these sections are presented on the revised plates.

Comment #5

Geotechnical cross sections A-A' and B-B' do not appear to coincide with the corresponding cross sections provided with the slope stability analyses. Verify and make revisions as necessary.

Response #5

The stability analyses for cross sections A-A' and B-B' presented in our August 8, 2001 report pertain to portions of the slopes near the southern bridge abutments. The critical failure surface and strength parameters used in the analyses are shown on each stability analyses section on Plate 19. The slope stability analyses section should provide clarification regarding the locations of the analyses for Sections A-A' and B-B'.

Comment #6

Show the depth and limits of surficial slumps (shown on the geotechnical map) on cross section L-L'.

Response #6

The mapped limits of the surficial slumps on and adjacent to Section L-L' are shown on Plate 14R. The shallow depth of these surficial slumps (estimated to be less than 10 feet) are of small scale with respect to the 100 scale map and sections included in this report. Accordingly, the depth limits are not shown on Section L-L' due to graphical constraints. However, the influence of these shallow failures was considered in assessing the need for mitigation for gross stability of the daylight cut at the top of the natural slopes.

Comment #7

Show the critical failure planes used in the slope stability analyses on the geotechnical map.

Response #7

The critical failure planes used in the stability analysis are shown in section on Plates 19 and 20, and 21 which are attached to this response letter. The critical failure surface and strength parameters used in the analyses are shown on each stability analyses section.

Comment #8

Ultimate shear strength parameters must be used in static and surficial slope stability analyses. Indicate the type of shear strength parameters (i.e., ultimate, peak, etc.) representative of bedrock (cross-bedding) and fill material used in the slope stability analysis.

Comment #9

In order to estimate "along bedding" shear strengths based on re-shear test results, the sample must be re-sheared several times until two consecutive runs yield the same shear value. Provide additional data to show that the residual shear strengths (Plate B-9) are representative of the lowest values based on the above criteria.

Comment #10

The shear strength values representative of slide plane material (obtained from back-calculation) appear high. Provide additional data to further substantiate these values. Make revisions as necessary.

Comment #11

The cohesion (4000 psf) representative of bedrock (C-1) is far greater than the values obtained from direct shear testing. Verify and make revisions as necessary.

Response to Comments 8, 9, 10 and 11

The material properties used in the slope stability analysis are summarized in the Table C-1 (revised), which is presented below.

Table C-1 (Revised)

Condition	Moist Density (pcf)	Saturated Density (pcf)	Friction Angle (deg)	Cohesion (psf)
Parallel Bedding	120	130	24	150
Cross Bedding	120	130	28	4000
Fill Material	120	130	33	120
Landslide - Slide Plane	120	130	25	0

The following presents clarification regarding the shear strength parameters used in the slope stability analyses for the various types of materials.

Engineered Fill: The shear strength parameters used in the stability analyses for engineered fill are based on saturated direct shear tests conducted on samples of the on-site materials remolded to approximately 90 percent relative compaction. The values used in the analyses are based on the ultimate shear strength of the tested soil samples. The direct shear test data presented in Appendix B of our August 8, 2001 report included the peak strengths of the soils samples. Plates B-10 through B-17, Direct Shear Test, which are attached to this letter, present the ultimate shear strength test results of the samples tested. The values used in the slope stability analyses are conservative relative to the direct shear tests results.

Parallel Bedding: The shear strength parameters used in the stability analyses for along bedding or parallel bedding conditions are based on saturated residual direct shear tests conducted on samples of the on-site materials. The residual direct shear tests were conducted by remolding a sample of sandy clay to a wet density of approximately 125 pcf, saturating the sample, and shearing the same sample three times. Plates B-9 from our August 8, 2001 has been updated to show the results of the three direct shear test runs and the values used in our analyses. Based on our review of the data the last two ultimate shear strengths runs of the sample were similar. In addition, the final ultimate shear strength parameters used in our analyses are considered to be

the residual shear strength parameters and conservatively representative of the potential along bedding shear strength of the siltstone bedrock soils.

Landslide Slide Plane: The shear strength parameters used in our analyses of the landslide surfaces were obtained by back-calculating the shear strength of the slide plane based on an assumed factor of safety of 1.0. The results of the back-calculation of the mapped slides shown in Sections C-C', P-P, Q-Q', and U-U' (formerly AA-AA') are attached to this letter. The material parameters for these sections, all of which are existing landslides, were arrived at by performing a back analysis approach. From our analysis a cohesion value of 0 pounds per square foot and internal angle of friction of at least 25 degrees were evaluated to be appropriate parameters for the slide failure plane for the landslide analysis.

Cross Bedding: The cross bedding shear strength parameters of the Kcs formation that were used in our analyses were evaluated by 1) conducting unconfined compressive strength tests and triaxial compression tests on representative samples of bedrock core samples and by 2) geomechanic classification of the rock masses by methods after Z.T Bieniawski, 1989. Direct shear tests were initially conducted on samples of the bedrock materials obtained from the borings. However, the results of the direct shear tests are not considered to be as representative of the actual shear strengths of the materials as by the previously mentioned methods are considering that 1) the samples obtained were significantly disturbed by the sampling process due to the cementation of the rock. These values were only applied for deep-seated rotational failure of slopes in which the potential failure surface would extend beneath surficial, weathered and fractured sandstone.

The results of the unconfined compressive strength and triaxial compression tests and the geomechanic classification of the rock masses are presented in our August 8, 2001 report. Based on the unconfined compression and triaxial shear strength tests, the samples had strengths that exceeded the limits of the equipment which had a capacities of 262 ksf for the unconfined compression equipment and approximately 80 ksf for the triaxial shear test device.

The values used in the slope stability analyses are conservative relative to the direct shear tests results.

Landslide Slide Plane: The shear strength parameters used in our analyses of the landslide surfaces were obtained by back-calculating the shear strength of the slide plane base on an assumed factor of safety of 1.0. The results of the back-calculation of the mapped slides shown in Sections C-C' and Q-Q' are attached to this letter. The material parameters for the section at C-C', P-P', Q-Q, and U-U' (formerly AA-AA'), all of which are existing landslides were arrived at by performing a back analysis approach. From our analysis a cohesion value of 0 pounds per square foot and internal angle of friction of 25-degrees were evaluated to be appropriate parameters for the slide failure plane for the landslide analysis.

Ultimate Shear Strengths: Ultimate shear strength values were only used of analysis of undisturbed natural slopes and cut slopes along bedding. More conservative residual values were used for along-bedding strengths and in conjunction with back-analyses for existing failure surfaces. Cross-bedding strengths were selected based upon direct shear and unconfined compressive strength values for undisturbed samples.

Number of Reshears to Estimate Residual Strengths: We concur that residual strength values may be underestimated by performing an inadequate number of reshears until the true residual, or assymtotic value is reached. We reviewed our direct shear test procedure an verified that shears were performed a minimum of six times and not as three times as shown on former test results.

High Slide Plane Values: The shear strength of rupture surface of existing failures was estimated by comparing remolded, residual direct shear values from hand-selected samples collected while downhole logging to back-analyzed values for landslide Qls-1. As discussed with you and as described in our response to question 1 of the Engineering Geology review sheet, we have re-analyzed our back-analysis for Qls-1 assuming no passive wedge. Results of that re-analysis are discussed in that response.

4000 psf Cohesion for Across-Bedding in Bedrock: This value was estimated by comparing laboratory-determined unconfined compressive strength values to broadly accepted values for similarly indurated sandstone using Goodman. These values were only applied for deep-seated rotational failure of slopes in which the potential failure surface would extend beneath surficial, weathered and fractured sandstone. We feel this value is representative of the these conditions after reviewing our methods.

Comment #12

Provide input/output data sheets for all slope stability analyses conducted.

Response #12

The input and output computer files of the stability analyses are provided to the County on a computer disk along with hard copies of the files. The hard copies of the input/output files are presented in a binder as a part of this response letter.

Comment #13

Provide static and seismic slope stability analysis for cross section C-C' considering failure of Qls-1. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.

Response #13

Slope stability analyses of Section C-C' was performed considering failure of Qls-1. The stability analysis conducted to evaluate Section C-C' and the RUA for Cut Slope 5 and Natural Slope 4 included an evaluation of geologic Cross Sections C-C', C2-D", and D-D". The summary of the analysis are presented in Table 1 (Revised) and the calculations are attached. The limits of the RUA are based upon the analysis of these sections considering; 1) That Qls-1 will remain, and 2) that Qls-1 fails completely and the debris is totally removed. Based upon our analysis the critical condition is with the Qls-1 debris remaining on the slope. The recommended limits of the RUA are shown on Plate 13R and in section on Plate 15R. The critical analysis are presented on in section on Plate 19.

Comment #14

Provide static and seismic slope stability analysis for cross section G-G' considering failure of the portion of Qls-2 downslope of reinforced keyway. Analysis must consider geotextile reinforcement where applicable. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in the slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.

Response #14

Slope stability analyses of Section G-G' was performed considering failure of Qls-2. The results of the analyses are presented in Table 1 (Revised) and the calculations are attached. For our analysis of the geotextile reinforced slope we initially designed the reinforced stabilization key to have an internal factor of safety of 1.5 and 1.1 (Minimum) static and pseudostatic respectively. We then evaluated the potential failure plane along the backcut of the engineered reinforced stability fill and along bedding at the heel of the daylight shear key. Satisfactory factors of safety greater than those required were calculated.

The analysis for the geotextile reinforcement stabilization was conducted using the STABLE 6H program. Based upon this analysis the reinforcement should consist of 14 layers of Tensar UX1700HS (or equivalent), with a minimum embedment length of 40 feet wide and at vertical intervals of 4 feet. The stability calculations are attached and the results are summarized on Plate 19, which includes the strength parameters used, the critical failure plane, and the calculated factor of safety.

Comment #15

Provide static and seismic slope stability analyses for cross section M-M' considering the recommended mitigative measures (i.e. MSE wall, drilled piers and fill). Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in the slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.

Response #15

Additional stability analyses were conducted to evaluate the recommended mitigation measure for Section M-M' which consist of a geotextile (geogrid) reinforced slope. For preliminary design purposes we evaluated the required geotextile reinforcement embedment lengths, and type using the Miraslope V. 2.33 program. Based upon our analysis the minimum reinforcement needed to obtain the required calculated factor of safety consist of 16 layers of Mirafi 10 XT (or equivalent), 60 feet wide placed at vertical intervals of 4 feet. The backcut will need to be laid back to a 2:1 (H:V) inclination. The analysis of the slope and cross sections are summarized on Table 1 (Revised) and the calculations are attached. With this measure the retaining walls may be supported on spread footings or MSE walls.

Comment #16

Provide static and slope stability analysis for cross sections P-P' and Q-Q' considering failure of Qls-3. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.

Response #16

Slope stability analyses of Section P-P' and Q-Q' was performed considering failure of Qls-3. The results of the analyses are presented in Table 1 (Revised) and the calculations are attached. Based on the stability analyses, the failed slope (Qls-3) is considered unstable without mitigation. Recommended mitigation of Qls-3 and this slope includes complete removal of the

slide debris and rebuilding the slope as a stability fill slope founded on a 25 ft. wide x 5ft. deep fill key as shown on the revised sections and plates. The stability calculations are attached and the results are summarized on Plate 19 through 21, which includes the strength parameters used, the critical failure plane, and the calculated factor of safety.

Comment #17

Provide volume calculations for the anticipated amount of slide debris generated by failure of QIs-3 to verify the capacity of the proposed debris basin. Make revisions as necessary.

Response #17

Please refer to Response #16. The slide material is recommended to be overexcavated and the slope rebuilt at 2:1 (h:v). Accordingly, slide debris volume calculations are not warranted at this time.

Comment #18

Provide static and seismic slope stability analysis for the steep natural slope shown on cross section U-U'. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.

Response #18

Please refer to our response to Geologic Review Sheet, Comment No. 7. The stability calculations have been modified accordingly and are attached.

Comment #19

Provide data and analyses to determine liquefaction potential of the on-site soils in the area of the proposed bridges. Also, evaluate the potential for seismically induced settlement (dry and saturated soils), lateral spreading, surface manifestation, etc. The analyses must be performed for soils within the upper 50 feet, as a minimum, for shallow foundation, or greater depth where deep foundation and/or subterranean structure is proposed. The historic-high water table shall be used in the analyses, unless other information is provided which indicates a higher or lower level is appropriate. Recommend mitigation as necessary. The liquefaction data and analyses must conform to the State of California Division of Mines and Geology "Special Publication 117", dated 1997 and "Recommended Procedure For Implementation of DMG Special Publication 117", dated March 1999.

Response #19

Please refer to our response to Geologic Review Sheet Comment No. 13.

Comment #20

Additional slope stability analysis may be required when the geology of the site is conclusively determined.

Response #20

Comment noted. We trust that our response is consistent with discussion at our meeting with you on October 1, 2001. If any additional concerns come to your attention, we would hope that you would call us and ask for additional data/analysis, as needed, prior to completion of a favorable review. We believe that close interaction initiated at our meeting with you and available from that point forward will reduce unnecessary use of your time and delays to the project.

Comment #21

Requirements of the Geology Section are attached.

Response #21

Comment noted.

Geology Section Review: Responses are provided in previous sections of this letter.

Comment #22

Include a copy of this review sheet with your response.

Response #22

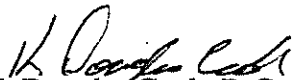

A copy of the review sheet is attached.

Copy of Review Sheets: A copy of both review sheets is included in Appendix C, herein.

We trust that our Engineering Geologic and Soils Engineering responses are consistent with discussions during our October 1, 2001 meeting and that they fully document any outstanding issues required for approval of the Tentative Tract Map. If you require any further information, please do not hesitate to contact either of the undersigned, at your convenience.

Respectfully submitted,

KLEINFELDER, INC.

K. Douglas Cook, R.G., C.E.G. I.
Senior Engineering Geologist

Justin J. Kempton, P.E., G.E.
Manager, Geotechnical Engineering

TENTATIVE TRACT 53138
SUBDIVIDER Presidio Chatsworth Partners LLC
ENGINEER B & E Engineers
GEOLOGIST Kleinfelder (58-919401-008)
SOILS ENGINEER Same as above

TENTATIVE MAP DATED 8/2/01
ADDRESS north end of Canoga Ave. at 118 Freeway
LOCATION Chatsworth
REPORT DATES 8/8/01, 4/24/00
REPORT DATES 8/8/01, 4/24/00

The Regional Planning Commission, developer and engineer are advised that:

PRIOR TO RECOMMENDING APPROVAL OF THE TENTATIVE TRACT OR MINOR LAND SUBDIVISION MAP:

Provide additional surface and/or subsurface investigation to more fully define the limits of the currently mapped landslides and depth to slide planes, particularly Qls-1. The extent of the proposed Restricted Use Areas associated with landslides Qls-1 and Qls-2 are highly dependent on the limits of these slides and their respective slide plane geometries therefore, further definition of the mapped slides, particularly Qls-1, is warranted. Projection of the Qls-1 rupture surface along bedding as shown on Cross Section C-C' suggests this landslide extends much further upslope than currently shown.

Prior to allowing any grading within Restricted Use Areas, the consultant must clearly demonstrate the following: a) any proposed grading will not worsen existing conditions; b) adjacent property will not be adversely affected; c) the area subject to instability and the Restricted Use Area must be contained on the same lot; and d) the change in use will not worsen existing conditions, e.g., change from natural area to development requiring irrigation.

Extend Geologic Cross Section D - D' northerly to the bottom of Devil Canyon and further evaluate the stability of proposed lots and streets considering a) daylighted bedding along apparent dip and b) loss of support due to failure of landslide Qls 1. Recommend revised structural setbacks, restricted use areas and mitigation, if factors of safety do not meet County minimum standards.

4. Discuss the ability of the geotextile-reinforced keyway, shown on Geologic Cross Section G - G', to support the proposed lots considering complete failure and lack of support from Qls 2. Was this situation evaluated in the stability analyses? It appears that failure of the unmitigated portion of Qls 2 will undermine the proposed mitigation. Recommend additional mitigation, structural setbacks and restricted use areas, if factors of safety do not meet County minimum standards.

Provide further evaluation of the stability of the existing topography, the proposed fill slope and the proposed retaining walls, shown on Geologic Cross Section M - M', considering a daylighted bedding condition along both true dip and apparent dip of bedding. Recommend mitigation, if factors of safety do not meet County minimum standards.

Identify the locations and provide the logs for all trenches excavated by the consultants for this investigation or provide an explanation for the omission of these trenches from the submitted report. Only 21 of the reported 31 test pits excavated are shown on Plates 13 and 14 or included in the trench logs in Appendix A.

Please provide Cross Section AA - AA' referred to in Appendix C of the report. Identify the location and orientation of this section on Plates 13 and/or 14.

Recommend mitigation for all areas that do not meet County minimum standards for factors of safety. This includes, but may not be limited to, the psuedostatic analysis for block failure along Section K - K' and the psuedostatic analysis for circular failure with a buttress fill along Section Q - Q'.

Provide static and psuedostatic analyses to evaluate the factors of safety of Natural Slope #2 below the daylight cut slope shown on Geologic Cross Section U - U'. Analyses should consider both failure along bedding and across bedding. Recommend mitigation, structural setbacks and restricted use areas if factors of safety do not meet County minimum standards.

10. Prepare a geologic cross section, similar to Cross Section U - U', from Browns Canyon through the landslide of Natural Slope #2 to the top of the slope extending to at least proposed "J" Street. Provide stability analyses to determine static and psuedostatic factors of safety for failure along bedding, across bedding and considering failure and lack of support of the landslide below the proposed horse trail, Lots 164 - 168 and "B" Street. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do meet County minimum standards.

Prepare a geologic cross section oriented approximately north-south extending from "A" Street through boring KB-7 and Lot 486 down into and across the bottom of Devil Canyon. Provide stability analyses using appropriate shear strengths to determine static and psuedostatic factors of safety. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do not meet County minimum standards. The description of this rock slope in Appendix C indicates "the sandstone is generally very weak to weak rock."

TENTATIVE TRACT 53138
SUBDIVIDER Presidio Chatsworth Partners LLC
ENGINEER B & E Engineers
GEOLOGIST Kleinfelder (58-919401-008)
SOILS ENGINEER Same as above

TENTATIVE MAP DATED 8/2/01
ADDRESS north end of Canoga Ave. at 118 Freeway
LOCATION Chatsworth
REPORT DATES 8/8/01, 4/24/00
REPORT DATES 8/8/01, 4/24/00

PRIOR TO RECOMMENDING APPROVAL OF THE TENTATIVE TRACT OR MINOR LAND SUBDIVISION MAP:

2. Provide an additional geologic cross section between Sections N - N' and U - U' through Natural Slope #1 and proposed Fill Slope #3. Orient the section in the most critical direction (approximately east west) and extend the section from the bottom of Browns Canyon through Lots 173 - 179 and across "B" Street. Perform stability analyses using appropriate shear strengths to determine the static and pseudostatic factors of safety. Recommend mitigation, structural setbacks and/or restricted use areas if factors of safety do not meet County minimum standards.
3. Based on the State of California Seismic Hazard Maps, Oat Mountain Quadrangle, areas of the subject site are located in an area with a potential for liquefaction. Engineering geology and soils engineering reports must address the potential for liquefaction and ground failure with respect to the proposed bridges. Please refer to the attached Materials Engineering Division's "Interim Geology Review Guidelines for Ground Failure/Liquefaction" (GS045 Rev. 5/18/99). Provide this office with two (2) original copies of all reports for review and distribution to the State of California Division of Mines and Geology.

Prepared by 
Greg K. Johnson RG 5987, CEG 2050

Date 9/10/01

NOTICE: Public Safety, relative to geotechnical subsurface exploration, shall be provided in accordance with current codes for excavations, inclusive of the Los Angeles County Code, Chapter 11.48, and the State of California, Title 8, Construction and Safety Orders.

The "Manual for Preparation of Geotechnical Reports" prepared by County of Los Angeles, Department of Public Works is available on the Internet at the following address:
<http://dpw.co.la.ca.us/med/manual.pdf>

GROUND FAILURE/LIQUEFACTION (INTERIM GUIDELINES)

This guideline addresses the general engineering geology review of developments in areas that have been designated to have a potential for liquefaction and associated lateral spreading. The Los Angeles County Building Code, 1994 U.B.C., State of California Seismic Hazard Mapping Act (SHMA), DMG Special Publication SP117, California Seismic Hazard Mapping Regulations ("Article 10") and procedures developed through the Southern California Earthquake Center were utilized in developing this guideline. The State Mining and Geology Board recommends that "engineering geologists and civil engineers conduct the assessment of the surface and subsurface geological/geotechnical conditions at the site, including off-site conditions, to identify potential hazards to the project. It is appropriate for the civil engineer to design and recommend mitigation measures. It is also appropriate for both the engineering geologists and civil engineers to be involved in the implementation of the mitigation measures - engineering geologists to confirm the geological conditions and civil engineers to oversee the implementation of the approved mitigation measures".

- 1) An engineering geology report that addresses the potential for liquefaction and associated settlement and lateral spreading is generally required. The report must minimally include and consider the following:
 - a) A description of the proposed project's location, topographic relief, drainage, subsurface geologic conditions, and proposed grading.
 - b) A site plan of the subject site showing the locations of all test pits, borings, penetration test locations, and soil or rock samples obtained.
 - c) Local and regional geologic maps showing bedrock, alluvium, colluvium, soil material, faults, shears, joint systems, lithologic contacts, seeps or springs, and other pertinent geologic and soil features existing on and adjacent to the project site.
 - d) Logs of borings, test pits, or other subsurface data obtained. It is recommended that a minimum depth of 50 feet below the existing ground surface be investigated for liquefaction.

- e) Geologic cross sections depicting geologic structure, stratigraphy, and subsurface water conditions, supported by boring and/or trench logs at appropriate locations.
- f) The groundwater level to be used in the liquefaction analysis. Location and extent of groundwater, perched groundwater and historic high groundwater. The historic high groundwater level should be used, in the liquefaction analysis, unless information obtained indicates that an alternate level is appropriate.
- g) Description of seismic setting, historical seismicity and methods and/or sources used to determine earthquake ground-motion parameters used in the liquefaction analysis. For high occupancy structures it is common practice to use a deterministic seismic hazard analysis with a median-plus-one-standard-deviation (84th percentile) in developing ground motion estimates. The consulting engineering geologist must provide ground motion parameters using either the deterministic or probabilistic method as follows:

Probabilistic:

Earthquake magnitudes and associated peak ground accelerations (PGA) based upon simple prescribed parameter values (SPPV) generated by the Department of Conservation may be used. These maps are included in the Seismic Hazard Evaluation Reports issued by DMG. PGA is dependent on site conditions and several maps have been prepared to accommodate these differences. Refer to SP117 for further details.

In-lieu of utilizing SPPV, a site-specific probabilistic seismic hazard analysis can be performed, and can supersede the SPPV values of PGA. If a site-specific probabilistic hazard analyses is performed, earthquake magnitudes must be based upon the current California Division of Mines and Geology Fault Model (fault catalog), with associated PGA utilizing recently published attenuation equations, and a probabilistic seismic hazard analysis (PSHA) utilizing a hazard level of at least 10 percent probability of exceedance in 50 years. All input and output data files (Dat,Out,Raw) associated with the computer program (e.g. FRISKSP) must accompany the geotechnical report as hard copies.

Any modifications to the program, standard user-selected input parameters, or the current California of Division Mines and Geology Fault Model, must be justified. It is important that the difference in duration of various earthquake magnitudes be accounted for when performing liquefaction analysis. Therefore, magnitude weighting must be performed per Idriss (1985)*. Magnitude Weighting Factors used in FRISKSP should be equivalent to the inverse of the Magnitude Scaling Factors used in the engineering analysis for liquefaction. Attenuation equations and values must reflect the use of current literature and site conditions. Attenuation relations produced by Campbell (1997), Joyner & Boore (1997), and Sadigh, et al. (1997) are acceptable** using the standard deviation on the attenuation functions. The geotechnical consultants must conduct the analysis utilizing all three of the above attenuation relations and then submit a discussion and conclusions justifying the seismic parameters utilized in the liquefaction analysis. The geotechnical consultants must justify all input parameters and certify the integrity of the data and program utilized in generating magnitudes and peak ground accelerations.

-OR-

Deterministic:

Earthquake magnitudes based upon the current California Division of Mines and Geology Fault Catalog, with associated PGA utilizing published attenuation equations and a deterministic seismic hazard analysis (DSHA). Attenuation equations and values must reflect the use of current literature and site conditions. Attenuation relations produced by Campbell (1997), Joyner & Boore (1997), and Sadigh, et al. (1997) are acceptable**. The geotechnical consultants should utilize the average ground motion obtained from the three attenuation relations in the liquefaction analysis. Again for high occupancy structures it is common practice to use a deterministic seismic hazard analysis with a median-plus-one-standard-deviation (84th percentile) in developing ground motion estimates.

NOTE: The results of the submitted site-specific seismic hazard analyses will be reviewed by utilizing a probabilistic seismic hazard analysis (PSHA), a hazard level of 10 percent probability of exceedance in 50 years, the current California Division of Mines and Geology Fault Catalog, the most updated version of FRISKSP by Thomas F. Blake, attenuation relations produced by Campbell (1997), Joyner & Boore (1997), and Sadigh, et al. (1997), and standard user-selected input parameters unless otherwise justified by the geotechnical consultants. Seismic parameters recommended by the geotechnical consultants are acceptable if they are greater than or equal to values obtained using these criteria.

- h) Consideration of the geologic factors that may control or affect the severity of potential hazards (e.g., site-specific response characteristics due to amplification of soft soils, deep sedimentary basins, topography, near-source affects, etc.)
 - i) The engineering geology report must comply with and contain a finding in accordance with Sections 110 and 111 of the Los Angeles County Building Code.
 - j) Discussion of proposed mitigation measures, if any, necessary to reduce potential damage caused by liquefaction.
 - k) Consideration of general guidelines of the DMG "Notes 42, 44, and 48."
2. For "projects" governed under the State of California SHMA and Article 10 (Section 3724).
- a) The required report(s) shall be prepared by a certified engineering geologist and/or registered civil engineer, having competence in the field of seismic hazard evaluation and mitigation.
 - b) The required report(s) shall be reviewed by a certified engineering geologist and/or registered civil engineer, having competence in the field of seismic hazard evaluation and mitigation.
 - c) A copy of all geotechnical reports must be sent to the State Geologist within 30 days of plan approval.

Review of:

Tentative Tract Dated By Regional Planning 8/2/01
Soils Engineering Report Dated 8/8/01 Geologic Report Dated 8/8/01

Previous review sheet dated 7/9/01

ACTION:

Tentative Map feasibility is not recommended for approval.

REMARKS:

1. Provide a geotechnical update report/letter which specifically addresses and evaluates the latest tentative tract map submitted through the Department of Regional Planning.
2. Provide a geotechnical map with corresponding cross sections which utilizes the current tentative map as a base.
3. Clearly show the following on the geotechnical map and corresponding cross sections:
 - a. Existing and proposed grades.
 - b. Lot lines.
 - c. Approximate limits and depth of removal and recompaction of slide debris and unsuitable soils.
 - d. Grading required for construction of buttress/stabilization fills, including areas of geotextile reinforcement.
 - e. Location of "Restricted Use Area(s)".
 - f. Mitigative measures, per the geotechnical engineer's recommendations.
4. Provide geotechnical cross sections AA-AA', CC-CC' and C3-C3' and identify their locations on the geotechnical map.
5. Geotechnical cross sections A-A' and B-B' do not appear to coincide with the corresponding cross sections provided with the slope stability analyses. Verify and make revisions as necessary.
6. Show the depth and limits of surficial slumps (shown on the geotechnical map) on cross section L-L'.
7. Show the critical failure planes used in the slope stability analyses on the geotechnical map. *Section*

SOILS ENGINEERING REVIEW SHEET.

Location Chatsworth

Sheet 2 of 3

REMARKS (cont.):

8. Ultimate shear strength parameters must be used in static and surficial slope stability analyses. Indicate the type of shear strength parameters (i.e. ultimate, peak, ect.) representative of bedrock (cross-bedding) and fill material used in the slope stability analysis.
9. In order to estimate "along bedding" shear strengths based on re-shear test results, the sample must be re-sheared several times until two consecutive runs yield the same shear value. Provide additional data to show that the residual shear strengths (Plate B-9) are representative of the lowest values based on the above criteria.
10. The shear strength values representative of slide plane material (obtained from back-calculation) appear high. Provide additional data to further substantiate these values. Make revisions as necessary.
11. The cohesion (4000 psf) representative of bedrock (page C-1) is far greater than the values obtained from direct shear testing. Verify and make revisions as necessary.
2. Provide input/output data sheets for all slope stability analyses conducted.
13. Provide static and seismic slope stability analysis for cross section C-C' considering failure of Qls-1. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.
14. Provide static and seismic slope stability analysis for cross section G-G' considering failure of the portion of Qls-2 downslope of reinforced keyway. Analysis must consider geotextile reinforcement where applicable. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.
15. Provide static and seismic slope stability analysis for cross section M-M' considering the recommended mitigative measures (i.e. MSE wall, drilled piers and fill). Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.
6. Provide static and slope stability analysis for cross sections P-P' and Q-Q' considering failure of Qls-3. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.
7. Provide volume calculations for the anticipated amount of slide debris generated by failure of Qls-3 to verify the capacity of the proposed debris basin. Make revisions as necessary.

LAND DEVELOPMENT DIVISION

SOILS ENGINEERING REVIEW SHEET

Location Chatsworth

Sheet 3 of 3

REMARKS (cont.):

18. Provide static and seismic slope stability analysis for the steep natural slope shown on cross section U-U'. Also, provide a geotechnical cross section showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Revise mitigation if factors of safety are below County minimum standards.
19. Provide data and analyses to determine liquefaction potential of the on-site soils in the area of the proposed bridges. Also, evaluate the potential for seismically induced settlement (dry and saturated soils), lateral spreading, surface manifestation, etc. The analyses must be performed for soils within the upper 50 feet, as a minimum, for shallow foundation, or greater depth where deep foundation and/or subterranean structure is proposed. The historic-high water table shall be used in the analyses, unless other information is provided which indicates a higher or lower level is appropriate. Recommend mitigation as necessary. The liquefaction data and analyses must conform to the State of California Division of Mines and Geology "Special Publication 117", dated 1997 and "Recommended Procedure For Implementation of DMG Special Publication 117", dated March 1999.
20. Additional slope stability analysis may be required when the geology of the site is conclusively determined.
21. Requirements of the Geology Section are attached.
22. Include a copy of this review sheet with your response.

Date 9/25/01

NOTICE: Public safety, relative to geotechnical subsurface exploration, shall be provided in accordance with current codes for excavations, inclusive of the Los Angeles County Code, Chapter 11.48, and the State of California, Title 8, Construction Safety Orders.

APPENDIX D
SUMMARY OF NATURAL AND PROPOSED SLOPES

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
Natural Slopes			
1 – Natural Slope	Below Lots 173 through 179	1½:1 to 2:1 natural slope	Kcs steeply oriented unfavorably out of slope, toward Browns Canyon
2 – Natural Slope	U-U' Below Lots 166 through 172	1 ½:1 to 1¼:1 natural slope	Kcs bedrock, with interbedded siltstone and some claystone, oriented steeply out of slope
3 – Natural Slope	Below Lots 141 through 144, and 164 through 166	1 ½:1 to 1¼:1 natural slope, small fill slope near "B" Street with 10 foot high retaining wall at the toe	Surficial debris on steep slope faces, Kcs bedrock, with interbedded siltstone and some claystone, oriented unfavorably out of slope, alluvial removals on the order of 3 to 5 feet anticipated
4 – Natural Slope	C-C'	190 Feet high, 280 feet long, 2:1 natural slope.	Slope contains wedge failure and potential block glide landslide. Lots 54 and 55 will be impacted by an existing head scarp and or extreme surficial slope instability. Kcs bedrock is oriented unfavorably out of slope. Recommend 100 foot structural setback restricted use area.
4 – Natural Slope	E-E'	130 Feet high, 240 feet long, 2:1 natural slope.	Kcs bedrock is oriented unfavorably out of slope, apparent dips 10 to 21 degrees
5 – Natural slope	G-G'	100 feet high, 200 feet long, 2:1 or flatter	Slope contains potential block glide landslide. Lots 26 through 29 will be impacted by surficial slope instability. Kcs bedrock oriented unfavorably out of slope, moderately dipping

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
6 – Natural Slope	B-B'	100 feet high, 210 feet long (west), 200 feet long (east), 2:1 or flatter near top, 1 ½:1 mid-slope to toe	Lineament from CDMG identified approximately 100 feet east of left (western) bridge abutment, Kcs bedrock is oriented unfavorably out of slope along western slope areas. Eastern slope areas are oriented favorably into slope, moderately to steeply dipping.
7 – Natural Slope	L-L'	240 feet high, 250 feet long with 35 feet high fill slope, 90 feet long.	Kcs bedrock oriented favorably into slope, slope debris on anti-dip slope facing Devil Canyon, removals anticipated to generate debris toward blue-line stream area during slope construction. Debris control measures should be implemented during grading.
8 – Natural Slope	F-F'	120 feet high, 110 feet long, 1 ½ :1 to midslope and 1:1 ½ immediately below the proposed cut lots 35 through 44	Kcs bedrock neutral orientation.

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
Cut Slopes			
1 – Cut Slope	O-O'	90 feet high, 200 feet long, 2:1 design with mid-slope benches	QTs bedrock consisting of sands and gravels of approximately 30 feet of top of slope, then cut will be in Kcs bedrock from mid-slope to toe of slope. Kcs bedrock is steeply dipping to the southwest. Fold axis of synform may be encountered near lower 1/3 of slope which changes bedding to be steeply dipping to the northeast. Fold area may need slope stability measures in this area.
1 – Cut Slope/back cut area	P-P'	2:1 cut slope design as referenced in O-O' (Cut Slope #1)	Slope western side and proposed debris basin may be impacted by landslide debris and tension cracks within QTs gravel and sandstone materials. Remove and replace landslide debris with 2:1 fill key (25'W x 5'D) at toe. Lay back landslide removal at toe of slope to 2:1.
2 – Cut Slope	N-N'	65 feet high, 220 feet long, 2:1 design with mid-slope bench and 6 foot retaining wall	Kcs bedrock steeply dipping 46 to 70 degrees to the southwest toward synform axis which changes bedding to be steeply dipping to the northeast. CDMG Fault crosses near top of slope. Fault is not anticipated to impact slope design.

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
Cut Slopes			
3 – Cut Slope	D-D'	70 feet high, 150 feet long, 2:1 proposed slope	Kcs bedrock oriented favorably into slope, apparent dips 24 to 46 degrees into slope. On north side of ridge below top of cut slope, Kcs bedrock oriented unfavorably out of slope. Slope contains wedge failure and potential block glide landslide. Slope instability not anticipated to impact slope design.
4 – Cut Slope	J-J'	70 feet high, 2:1 design with 40 foot high fill-over-cut slope	Kcs oriented favorably into slope, some alluvial removals on the order of 3 to 5 feet anticipated in west end of slope.

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
Fill Slopes			
1 – Fill Slope	K-K'	140 feet high, 355 feet long, 2:1 design slope	Kcs bedrock oriented unfavorably out of slope, alluvial removals anticipated in isolated areas on the order of 3 to 5 feet.
2 – Fill Slope	M-M'	90 feet high, 160 feet long, engineered retaining walls (10 to 30 feet high)/fill slope combination proposed	Kcs bedrock oriented unfavorably out of slope. Moderately to steeply dipping 19 to 56 degrees obliquely out of slope, alluvial removals at toe anticipated on the order of 5 to 8 feet. Retaining wall foundation depths not known at this time.
3 – Fill Slope	Below Lots 173 through 179	70 foot high, 155 foot long 2:1 slope design,	Kcs bedrock oriented steeply dipping toward natural slope #1. Typical fill key recommended at toe of fill slope. Some alluvial removals on the order of 4 to 5 feet anticipated through center of slope.

Analyses Number	File Name	Profile Name	Analyses Type	Condition	FS (Static)	FS (Pseudo-Static)	Description/Comments
1		A-A'	Parallel	South Slope Bridge Abutment	3.1	2.2	Existing condition stable, no improvements recommended
2		B-B'	Parallel	Southwest Slope Bridge Abutment	2.1	1.5	Existing condition stable, no improvements recommended
2		B-B'	Parallel	Southwest Slope Bridge Abutment (CDMG Tension crack)	2.3	1.6	Tension crack at the toe stability evaluation
3		C-C'	Qls Back Calc.	Existing landslide - Back Calculation of Slide Plane	1.0	N/A	Evaluation of existing conditions
3		C-C'	Parallel	Proposed Grades with Landslide Removed	1.0	<1.1	Evaluation of slope assuming failure of Qls-1 (removal of Slide Debris)
3		C-C'	Parallel	Proposed Grades with Landslide Removed	1.6	1.2	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed
3		C-C'	Parallel	Proposed Grades with Landslide In-Place	1.6	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
4		C2-D'	Parallel	Proposed Grades with Landslide Removed	<1.5	<1.1	Evaluation of existing conditions, FS<1.5; Slope mitigation (RUA) required
4		C2-D'	Parallel	Proposed Grades with Landslide Removed	1.7	1.3	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed (With Landslide In Place = Critical Case)
4		C2-D'	Parallel	Proposed Grades with Landslide In-Place	1.5	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
5		D-D'	Cross	South Facing Cut Slope 3	>1.5	>1.1	Stable by observation Cross Bedding no remediation required
6		D-D'	Parallel	Proposed Grades with Landslide Removed	<1.5	<1.1	Evaluation of existing conditions, FS<1.5; Slope mitigation (RUA) required
6		D-D''	Parallel	Proposed Grades with Landslide Removed	1.7	1.1	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide Removed
6		D-D''	Parallel	Proposed Grades with Landslide In-Place	1.7	1.2	Setback analysis for Qls-1 with setback measured from top of slope adjacent to Lot 55 - Landslide In-Place
7		E-E'	Parallel	Daylight cut at top of slope	1.6	1.2	Block analysis of entire slope
7		E-E'	Parallel	Daylight cut at top of slope	1.9	1.4	Infiltration at mid slope
7		E-E'	Parallel	Daylight cut at top of slope	2.5	1.5	Top of slope with 13 degree bedding plane analysis
8		F-F'	Cross	Daylight cut at top of slope	2.4	2.0	Circular Analyses with 5' tension crack
9		G-G'	Parallel	Daylight cut at top of slope/Qls-2	1.4	--	Evaluation of existing conditions, FS<1.5; Slope mitigation required
9		G-G'	Circular	Daylight cut shear key / Geogrid Reinforced Slope	1.5	1.1	Circular failure through geogrid slope (With Qls-2 Removed)
9		G-G'	Parallel	Daylight cut shear key / Geogrid Reinforced Slope	1.9	1.5	Along bedding failure at heel of reinforced shear key
10		H-H'	Cross	Fill Slope	>1.5	>1.1	Stable by observation and 1-1' Analysis
11		I-I'	Cross	Fill Slope	1.7	1.2	Assumed rotational failure below B' Street
11		I-I'	Cross	Fill Slope	1.8	1.3	Assumed mid-slope rotational failure above B' Street
12		J-J'	Cross	Fill over cut slope	>1.5	>1.1	Stable by observation, cross bedded slope
13		K-K'	Circular	Fill Slope	1.9	1.3	Bottom of fill slope
13		K-K'	Circular	Fill Slope	1.9	1.4	Middle of fill slope
13		K-K'	Circular	Fill Slope	2.0	1.4	Top of fill slope
13		K-K'	Parallel	Fill Slope	1.7	1.1	Sandstone Block Failure
14		L-L'	Cross	Fill over Natural Slope	1.8	1.5	Sandstone Circular failure
15		M-M'	Circular	Proposed Fill slope with Retaining Walls	<1.5	<1.1	Circular failure through engineered fill with retaining walls FS<1.5 and <1.1
15		M-M'	Circular	Proposed Fill slope with geogrid reinforcement	1.5	1.1	Circular failure through geogrid reinforced engineered fill
16		M2-M2'	Circular	Proposed Fill slope with geogrid reinforcement	2.3	>1.1	Block failure along backcut and bedding planes
17		N-N'	Syncline Parallel	Proposed Cut Slope	>1.5	>1.1	Stable by observation; Steeply dipping bedding
18		O-O'	Folded	Qls over Kcs Cut Slope	1.7	1.2	Folded bedrock circular analysis through toe of slope
18		O-O'	Parallel	Qls over Kcs Cut Slope	1.6	1.1	Folded bedrock block analysis

Slope Stability Analysis Summary Table

	O-O'	Circular	Qts over Kcs Cut Slope	1.7	1.3	Circular failure through Qts at top of slope
18	P-P'	Qts Back Calc.	Existing Landslide - Back Calculation	1.0	---	Specified Surface Spencers Method
19	P-P'	Qts Back Calc.	Existing Landslide - Back Calculation	0.9	---	Circular Failure Surface Bishops method
19	P-P'	Folded	2:1 layback in Qts over steepened slope	1.7	1.2	Circular failure in Qts after removal of Qls-3, FS<1.5; Slope mitigation required
19	P-P'	Circular	Replacement fill at Toe of Slope and 2:1 (H:V) lay back in Qts	1.7	1.2	Circular failure through Qts
20	U-U' formerly AA-AA'	Circular	Daylight Cut at Natural Slope 2	2.0	1.6	Circular analysis through toe of slope
20	U-U' formerly AA-AA'	Parallel	Daylight Cut at Natural Slope 2	1.5	1.2	Along bedding analysis through toe of slope
21	Q-Q'	Qts Back Calc.	Existing Landslide(Qls-3) - Back Calculation	1.0	---	Evaluation of existing conditions
21	Q-Q'	Folded	Qts over steepened slope	---	---	See Analyses for P-P'
22	R-R'	Cross	Cut Slope No. 2	>1.5	>1.1	Stable by Observation
23	S-S'	Cross	Cut Slope	>1.5	>1.1	Stable by Observation
24	T-T'	Parallel	Sandstone monument on slope with Retaining Wall at Toe of Slope	1.0	<1.1	Along Bedding Failure plane; FS<1.5, Mitigation Recommended
24	T-T'	Parallel	Sandstone monument on slope with Retaining Wall at Toe of Slope	1.5	1.1	Load that the wall is required to carry to achieve a FS=1.5: 13 kips / lf
24	T-T'	Parallel	Retaining Wall at Toe of Slope without Sandstone Monument	1.5	1.1	Load that the wall is required to carry to achieve a FS=1.5: 0.9 kips / lf
25	V-V'	Parallel	Existing Slope (Natural Slope 2)	1.5	1.3	Calculated setback distance for FS>1.5 and >1.1 (pseudo-static)
25	V-V'	Parallel	Existing Slope (Natural Slope 2)	<1.5	<1.1	Existing Slope FS<1.5 by Observation and evaluation of failure plane with FS=1.5
25	V-V'	Parallel	Existing Slope (Natural Slope 2)	>1.5	>1.1	Assumed failure plane at Daylight Cut Shear Key; FS >1.5 and >1.1 by Observation and evaluation of failure plane with FS>1.5 and >1.1
26	W-W'	Parallel	North Facing Natural Slope with Surficial failure Removed	1.9	1.6	Existing condition after Surficial Failure/Removal; assumed failure through top of slope
26	W-W'	Parallel	North Facing Natural Slope with Surficial failure Removed	1.6	1.3	Assumed failure plane through toe of slope after Surficial Failure/Removal
26	W-W'	Parallel	North Facing Natural Slope with Surficial failure Removed	1.5	1.1	Calculated Setback Distance; Assumed failure plane for FS=1.5 after Surficial Removal / Failure
27	X-X'	Circular	Fill Slope 3 over Natural Slope 1	2.8	2.2	Assumed circular failure near toe of slope
28	Y-Y'	Circular	Cut Slope No. 2	2.0	1.4	Circular failure through Qts; cut slope
Notes:	See Geologic Cross Section for left or right reference do not look at slope stability analysis sheets. This average value represents the entire slope ht. See geologic profiles for details					
	For the Pseudo Static cases a horizontal coefficient Kh=0.15 and Kv=0.0 was used in the analysis

5	1680.0	1170.0	1730.0	1175.0	1

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight (pcf)	Moist Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 4

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-25.00	4000.0	28.00
2	10.00	4000.0	28.00
3	35.00	150.0	24.00

4 90.00 4000.0 28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

400 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

***** DEFAULT SEGMENT LENGTH SELECTED BY XSTABL *****

Length of line segments for active and passive portions of sliding block is 8.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1610.0	1127.0	1630.0	1135.0	15.0
2	1675.0	1163.0	1692.0	1165.0	10.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

 ** Factor of safety calculation for surface # 7 **

The trial failure surface in question is defined by the following 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1621.31	1142.07
2	1627.18	1138.27
3	1677.47	1163.15
4	1681.83	1169.86
5	1682.06	1170.21

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1609.24	1135.00
2	1611.78	1133.35
3	1690.55	1167.57
4	1692.97	1171.30

** Corrected JANBU FOS = 3.068 ** (Fo factor = 1.013)

Failure surface No. 2 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.95	1135.60
2	1612.05	1134.88
3	1689.77	1166.73
4	1692.72	1171.27

** Corrected JANBU FOS = 3.182 ** (Fo factor = 1.016)

Failure surface No. 3 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.86	1135.54
2	1612.75	1134.31
3	1678.75	1168.03
4	1680.03	1170.00

** Corrected JANBU FOS = 3.215 ** (Fo factor = 1.012)

Failure surface No. 4 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1608.88	1135.00
2	1610.05	1134.24
3	1687.09	1167.05
4	1689.64	1170.96

** Corrected JANBU FOS = 3.223 ** (Fo factor = 1.014)

Failure surface No. 5 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1608.17	1135.00
2	1611.30	1132.97

3	1618.01	1128.61
4	1690.59	1168.55
5	1692.33	1171.23

** Corrected JANBU FOS = 3.317 ** (Fo factor = 1.045)

Failure surface No. 6 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1606.74	1135.00
2	1612.78	1131.07
3	1684.57	1168.84
4	1685.69	1170.57

** Corrected JANBU FOS = 3.332 ** (Fo factor = 1.032)

Failure surface No. 7 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1609.90	1135.00
2	1611.15	1134.19
3	1684.10	1166.28
4	1686.97	1170.70

** Corrected JANBU FOS = 3.337 ** (Fo factor = 1.016)

Failure surface No. 8 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.36	1135.23
2	1611.99	1134.17
3	1618.70	1129.81
4	1687.37	1167.66
5	1689.50	1170.95

** Corrected JANBU FOS = 3.353 ** (Fo factor = 1.042)

Failure surface No. 9 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.83	1135.52
2	1615.06	1132.77
3	1685.34	1166.55
4	1688.11	1170.81

** Corrected JANBU FOS = 3.374 ** (Fo factor = 1.023)

Failure surface No.10 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1606.96	1135.00
2	1608.81	1133.80
3	1615.52	1129.44
4	1689.29	1167.88
5	1691.41	1171.14

** Corrected JANBU FOS = 3.412 ** (Fo factor = 1.040)

**
** Out of the 400 surfaces generated and analyzed by XSTABL, **
** 54 surfaces were found to have MISLEADING FOS values. **
**

The following is a summary of the TEN most critical surfaces

Problem Description : Section A-A' Parallel Bedding

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)
1.	3.068	1.013	1609.24	1692.97	7.083E+04
2.	3.182	1.016	1610.95	1692.72	6.382E+04
3.	3.215	1.012	1610.86	1680.03	4.431E+04
4.	3.223	1.014	1608.88	1689.64	5.786E+04

Problem Description : Section A-A' Parallel Bed. (Kh=0.15)

 SEGMENT BOUNDARY COORDINATES

5 SURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	1570.0	1140.0	1590.0	1135.0	1
2	1590.0	1135.0	1610.0	1135.0	1
3	1610.0	1135.0	1650.0	1160.0	1
4	1650.0	1160.0	1680.0	1170.0	1
5	1680.0	1170.0	1730.0	1175.0	1

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 4

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-25.00	4000.0	28.00
2	10.00	4000.0	28.00
3	35.00	150.0	24.00

4 90.00 4000.0 28.00

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

400 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

***** DEFAULT SEGMENT LENGTH SELECTED BY XSTABL *****

Length of line segments for active and passive portions of sliding block is 8.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1610.0	1127.0	1630.0	1135.0	15.0
2	1675.0	1163.0	1692.0	1165.0	10.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

 ** Factor of safety calculation for surface # 18 **
 ** failed to converge within FIFTY iterations **
 **
 ** The last calculated value of the FOS was 8.0902 **

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1609.24	1135.00
2	1611.78	1133.35
3	1690.55	1167.57
4	1692.97	1171.30

** Corrected JANBU FOS = 2.229 ** (Fo factor = 1.013)

Failure surface No. 2 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.95	1135.60

2	1612.05	1134.88
3	1689.77	1166.73
4	1692.72	1171.27

** Corrected JANBU FOS = 2.259 ** (Fo factor = 1.016)

Failure surface No. 3 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1608.88	1135.00
2	1610.05	1134.24
3	1687.09	1167.05
4	1689.64	1170.96

** Corrected JANBU FOS = 2.316 ** (Fo factor = 1.014)

Failure surface No. 4 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1609.90	1135.00
2	1611.15	1134.19
3	1684.10	1166.28
4	1686.97	1170.70

** Corrected JANBU FOS = 2.421 ** (Fo factor = 1.016)

Failure surface No. 5 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.86	1135.54
2	1612.75	1134.31
3	1678.75	1168.03
4	1680.03	1170.00

** Corrected JANBU FOS = 2.435 ** (Fo factor = 1.012)

Failure surface No. 6 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1612.70	1136.69
2	1614.16	1135.74
3	1687.06	1165.99
4	1690.34	1171.03

** Corrected JANBU FOS = 2.489 ** (Fo factor = 1.018)

Failure surface No. 7 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1612.10	1136.31
2	1614.06	1135.04
3	1691.32	1165.28
4	1695.39	1171.54

** Corrected JANBU FOS = 2.490 ** (Fo factor = 1.022)

Failure surface No. 8 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1610.83	1135.52
2	1615.06	1132.77
3	1685.34	1166.55
4	1688.11	1170.81

** Corrected JANBU FOS = 2.514 ** (Fo factor = 1.023)

Failure surface No. 9 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1611.90	1136.19
2	1613.91	1134.89
3	1684.62	1166.11
4	1687.64	1170.76

** Corrected JANBU FOS = 2.523 ** (Fo factor = 1.017)

Failure surface No.10 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1608.17	1135.00
2	1611.30	1132.97
3	1618.01	1128.61
4	1690.59	1168.55
5	1692.33	1171.23

** Corrected JANBU FOS = 2.528 ** (Fo factor = 1.045)

 **
 ** Out of the 400 surfaces generated and analyzed by XSTABL, **
 ** 19 surfaces were found to have MISLEADING FOS values. **
 **

The following is a summary of the TEN most critical surfaces

Problem Description : Section A-A' Parallel Bed. (Kh=0.15)

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)

5	1660.0	1270.0	1710.0	1270.0	1
6	1710.0	1270.0	1760.0	1280.0	1

 A CRACKED ZONE HAS BEEN SPECIFIED

Depth of crack below ground surface = 5.00 (feet)
 Maximum depth of water in crack = 4.00 (feet)
 Unit weight of water in crack = 62.40 (pcf)

Failure surfaces will have a vertical side equal to the specified depth of crack and be affected by a hydrostatic force according to the specified depth of water in the crack

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight (pcf)	Moist Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

A critical failure surface searching method, using a random

technique for generating CIRCULAR surfaces has been specified.

100 trial surfaces will be generated and analyzed.

10 Surfaces initiate from each of 10 points equally spaced
along the ground surface between x = 1400.0 ft
and x = 1460.0 ft

Each surface terminates between x = 1480.0 ft
and x = 1481.0 ft

Unless further limitations were imposed, the minimum elevation
at which a surface extends is y = .0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

2.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

```
*****

 AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 3205.91 (psf)
 Pore Water Pressure = .00 (psf)
 Shear Stress = 1524.70 (psf)

Total Length of failure surface = 397.79 feet

 For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = .980

Total shear strength available
along specified failure surface = 594.68E+03 lb

Section C-C
SPENCER'S METHOD, FOS for Specified Surface = .987

4	1515.00	.00	0.	-.17	.00	.000

 AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 1774.81 (psf)
 Pore Water Pressure = .00 (psf)
 Shear Stress = 952.79 (psf)

Total Length of failure surface = 107.82 feet

 For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = .987

Total shear strength available
 along specified failure surface = 101.38E+03 lb

 For the specified surface, the analysis computed the following:

Negative (tensile) Normal Effective Force = 0 slices
 Negative (tensile) Interslice Force = 1 slices
 Unreasonable Location of Interslice Force = 0 slices

In view of these errors, the computed FOS may be UNREASONABLE!

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

 ** Factor of safety calculation for surface # 55 **
 ** failed to converge within FIFTY iterations **
 **
 ** The last calculated value of the FOS was-385.1009 **
 ** This will be ignored for final summary of results **

The trial failure surface in question is defined by the following 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1164.70	1208.23
2	1174.64	1201.78
3	1189.74	1191.97
4	1501.54	1379.81
5	1505.87	1386.48

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	26.00	4000.0	28.00
2	30.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating sliding BLOCK surfaces, has been
specified.

The active and passive portions of the sliding surfaces
are generated according to the Rankine theory.

300 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

Length of line segments for active and passive portions of
sliding block is 18.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1175.0	1183.0	1196.0	1191.0	30.0
2	1500.0	1370.0	1530.0	1355.0	25.0

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero.

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined
are displayed below - the most critical first

Failure surface No. 1 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1169.83	1209.94

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

***** SIMPLIFIED JANBU METHOD *****

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1029.19	1203.06
2	1043.33	1192.43
3	1071.75	1186.68

4 1517.41 1351.00
5 1517.41 1354.00

** Corrected JANBU FOS = 1.115 ** (Fo factor = 1.025)

Failure surface No. 2 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1060.68	1215.99
2	1066.89	1212.32
3	1089.04	1193.61
4	1514.10	1351.00
5	1514.10	1354.00

** Corrected JANBU FOS = 1.137 ** (Fo factor = 1.029)

Failure surface No. 3 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1060.92	1216.12
2	1066.00	1211.52
3	1088.26	1192.94
4	1516.99	1351.00
5	1516.99	1354.00

** Corrected JANBU FOS = 1.141 ** (Fo factor = 1.029)

Failure surface No. 4 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1050.87	1210.49
2	1055.64	1209.97
3	1076.81	1190.15

-- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

11	1320.0	1312.0	1360.0	1312.0	1
12	1360.0	1312.0	1430.0	1312.0	1

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC
 Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	20.00	4000.0	28.00
2	24.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

750 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1070.0	1165.0	1140.0	1210.0	30.0
2	1275.0	1280.0	1350.0	1285.0	40.0

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)
*****
Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.
*****
```

 USER SELECTED option to maintain strength greater than zero

```

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 14 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1081.02	1190.68
2	1082.52	1189.45
3	1084.51	1189.38
4	1086.51	1189.37
5	1335.55	1298.14
6	1336.60	1299.84
7	1337.20	1301.75
8	1338.59	1303.19
9	1339.71	1304.84
10	1340.67	1306.60
11	1342.08	1308.01
12	1343.45	1309.47
13	1344.75	1310.99
14	1345.46	1312.00

** Corrected JANBU FOS = 1.640 ** (Fo factor = 1.014)

Failure surface No. 2 specified by 14 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1074.52	1190.00
2	1074.52	1190.00
3	1076.27	1189.02
4	1078.27	1188.96
5	1079.99	1187.95
6	1081.49	1186.62
7	1347.53	1299.95
8	1347.96	1301.90

10	1349.55	1305.54
11	1350.82	1307.08
12	1352.15	1308.58
13	1353.52	1310.04
14	1353.88	1312.00

** Corrected JANBU FOS = 1.682 ** (Fo factor = 1.013)

Failure surface No. 3 specified by 15 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
-----------	-------------	-------------

1	1098.01	1202.00
2	1099.73	1201.68
3	1101.33	1200.47
4	1103.21	1199.79
5	1105.12	1199.20
6	1106.63	1197.88
7	1347.14	1299.93
8	1348.55	1301.35
9	1349.58	1303.06
10	1350.99	1304.49
11	1352.40	1305.90
12	1353.38	1307.64
13	1353.84	1309.59
14	1354.63	1311.42
15	1354.74	1312.00

** Corrected JANBU FOS = 1.743 ** (Fo factor = 1.014)

Failure surface No. 4 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1110.09	1210.06
2	1110.89	1209.74
3	1112.31	1208.34
4	1114.30	1208.10
5	1339.35	1303.49
6	1339.72	1305.45
7	1340.88	1307.08
8	1342.24	1308.55
9	1342.99	1310.40
10	1344.27	1311.94
11	1344.32	1312.00

** Corrected JANBU FOS = 1.746 ** (Fo factor = 1.011)

Failure surface No. 5 specified by 17 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1093.00	1198.67
2	1093.41	1198.49
3	1095.26	1197.72
4	1096.80	1196.44

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	20.00	4000.0	28.00
2	24.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating sliding BLOCK surfaces, has been
specified.

750 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of
sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1070.0	1165.0	1140.0	1210.0	30.0
2	1275.0	1280.0	1350.0	1285.0	40.0

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)
*****
Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 14 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1081.02	1190.68
2	1082.52	1189.45
3	1084.51	1189.38
4	1086.51	1189.37
5	1335.55	1298.14
6	1336.60	1299.84
7	1337.20	1301.75
8	1338.59	1303.19
9	1339.71	1304.84
10	1340.67	1306.60
11	1342.08	1308.01
12	1343.45	1309.47
13	1344.75	1310.99
14	1345.46	1312.00

** Corrected JANBU FOS = 1.169 ** (Fo factor = 1.014)

Failure surface No. 2 specified by 14 coordinate points

Point	x-surf	y-surf
-------	--------	--------

No.	(ft)	(ft)
1	1074.52	1190.00
2	1074.52	1190.00
3	1076.27	1189.02
4	1078.27	1188.96
5	1079.99	1187.95
6	1081.49	1186.62
7	1347.53	1299.95
8	1347.96	1301.90
9	1348.52	1303.82
10	1349.55	1305.54
11	1350.82	1307.08
12	1352.15	1308.58
13	1353.52	1310.04
14	1353.88	1312.00

** Corrected JANBU FOS = 1.192 ** (Fo factor = 1.013)

Failure surface No. 3 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1110.09	1210.06
2	1110.89	1209.74
3	1112.31	1208.34
4	1114.30	1208.10
5	1339.35	1303.49
6	1339.72	1305.45
7	1340.88	1307.08
8	1342.24	1308.55
9	1342.99	1310.40
10	1344.27	1311.94
11	1344.32	1312.00

** Corrected JANBU FOS = 1.240 ** (Fo factor = 1.011)

Failure surface No. 4 specified by 15 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1098.01	1202.00
2	1099.73	1201.68
3	1101.33	1200.47
4	1103.21	1199.79
5	1105.12	1199.20
6	1106.63	1197.88
7	1347.14	1299.93
8	1348.55	1301.35
9	1349.58	1303.06
10	1350.99	1304.49
11	1352.40	1305.90
12	1353.38	1307.64
13	1353.84	1309.59
14	1354.63	1311.42
15	1354.74	1312.00

** Corrected JANBU FOS = 1.240 ** (Fo factor = 1.014)

Failure surface No. 5 specified by 17 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1093.00	1198.67
2	1093.41	1198.49

3	1095.26	1197.72
4	1096.80	1196.44
5	1098.36	1195.18
6	1099.92	1193.94
7	1344.71	1297.24
8	1345.95	1298.81
9	1346.80	1300.63
10	1348.11	1302.13
11	1348.64	1304.06
12	1349.52	1305.86
13	1350.93	1307.27
14	1352.35	1308.68
15	1353.44	1310.36
16	1354.77	1311.85
17	1354.80	1312.00

** Corrected JANBU FOS = 1.252 ** (Fo factor = 1.016)

Failure surface No. 6 specified by 21 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1080.22	1190.14
2	1081.08	1189.39
3	1082.60	1188.09
4	1084.56	1187.70
5	1085.98	1186.28
6	1087.84	1185.55
7	1089.71	1184.84
8	1341.93	1290.25
9	1343.02	1291.92
10	1344.06	1293.63
11	1344.56	1295.57
12	1345.61	1297.27
13	1346.15	1299.20
14	1347.28	1300.85
15	1348.55	1302.40
16	1348.72	1304.39

21	1353.50	1312.00

** Corrected JANBU FOS = 1.299 ** (Fo factor = 1.024)

Failure surface No. 7 specified by 17 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1094.66	1199.77
2	1096.12	1198.87
3	1097.71	1197.66
4	1334.25	1291.31
5	1335.38	1292.96
6	1336.53	1294.60
7	1337.54	1296.32
8	1338.37	1298.14
9	1339.42	1299.84
10	1340.14	1301.71
11	1341.04	1303.49
12	1342.15	1305.16
13	1343.37	1306.74
14	1344.72	1308.22
15	1345.44	1310.08
16	1346.59	1311.72
17	1346.66	1312.00

** Corrected JANBU FOS = 1.305 ** (Fo factor = 1.023)

Failure surface No. 8 specified by 17 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1106.22	1207.48
2	1108.03	1207.45
3	1110.02	1207.25
4	1112.01	1207.07
5	1113.77	1206.11
6	1115.30	1204.83
7	1116.91	1203.64
8	1118.91	1203.56
9	1345.79	1300.25
10	1347.07	1301.78
11	1348.48	1303.20
12	1349.89	1304.61
13	1349.91	1306.61
14	1350.96	1308.31
15	1352.37	1309.73
16	1352.95	1311.65
17	1353.05	1312.00

** Corrected JANBU FOS = 1.336 ** (Fo factor = 1.015)

Failure surface No. 9 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1115.44	1213.63
2	1116.27	1213.01
3	1117.94	1211.92
4	1119.93	1211.71
5	1323.82	1300.92
6	1325.16	1302.41
7	1326.40	1303.98
8	1327.80	1305.40
9	1329.07	1306.95
10	1330.46	1308.39
11	1331.82	1309.86
12	1333.23	1311.28
13	1333.90	1312.00

** Corrected JANBU FOS = 1.343 ** (Fo factor = 1.012)

Failure surface No.10 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1109.81	1209.88
2	1110.25	1209.52
3	1112.09	1208.75
4	1113.70	1207.56
5	1115.22	1206.25
6	1327.17	1300.17
7	1328.36	1301.79
8	1328.71	1303.75
9	1329.94	1305.34
10	1330.93	1307.07
11	1331.44	1309.01
12	1332.71	1310.55
13	1334.03	1312.00

** Corrected JANBU FOS = 1.354 ** (Fo factor = 1.015)

**
** Out of the 750 surfaces generated and analyzed by XSTABL, **
** 8 surfaces were found to have MISLEADING FOS values. **
**

The following is a summary of the TEN most critical surfaces

Problem Description : Section E-E' Kh=0.15

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)
1.	1.169	1.014	1081.02	1345.46	3.690E+05
2.	1.192	1.013	1074.52	1353.88	4.063E+05
3.	1.240	1.011	1110.09	1344.32	2.765E+05
4.	1.240	1.014	1098.01	1354.74	4.076E+05
5.	1.252	1.016	1093.00	1354.80	4.358E+05
6.	1.299	1.024	1080.22	1353.50	5.361E+05

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	20.00	4000.0	28.00
2	24.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

750 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1160.0	1215.0	1220.0	1245.0	30.0
2	1290.0	1300.0	1360.0	1300.0	20.0

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)
*****
Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.
*****
```

 USER SELECTED option to maintain strength greater than zero

```

17	1301.61	1312.00

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
-----------	-------------	-------------

1	1183.08	1246.54
2	1183.76	1246.10
3	1185.50	1245.11
4	1187.27	1244.19
5	1188.74	1242.83
6	1339.81	1306.75
7	1340.65	1308.56
8	1342.05	1309.99
9	1342.82	1311.83
10	1342.97	1312.00

** Corrected JANBU FOS = 1.899 ** (Fo factor = 1.015)

Failure surface No. 2 specified by 9 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1193.79	1252.53
2	1194.45	1252.14
3	1196.18	1251.14
4	1197.69	1249.83
5	1199.24	1248.57
6	1200.69	1247.19
7	1354.30	1309.71
8	1355.39	1311.39
9	1355.79	1312.00

** Corrected JANBU FOS = 1.942 ** (Fo factor = 1.020)

Failure surface No. 3 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1188.65	1249.33
2	1189.36	1248.62
3	1191.36	1248.53
4	1193.35	1248.39
5	1195.10	1247.43
6	1196.63	1246.14
7	1198.21	1244.91
8	1347.49	1308.46
9	1348.71	1310.04
10	1350.11	1311.47
11	1350.63	1312.00

** Corrected JANBU FOS = 1.946 ** (Fo factor = 1.020)

Failure surface No. 4 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1151.68	1233.89
2	1151.88	1233.74
3	1153.29	1232.33
4	1155.29	1232.31
5	1157.13	1231.52
6	1158.73	1230.31
7	1160.21	1228.97
8	1161.64	1227.57
9	1163.57	1227.04
10	1347.42	1307.95
11	1348.53	1309.61
12	1349.57	1311.32
13	1349.92	1312.00

** Corrected JANBU FOS = 1.975 ** (Fo factor = 1.023)

Failure surface No. 5 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1187.48	1248.74
2	1187.54	1248.69
3	1189.18	1247.54
4	1191.18	1247.41
5	1192.73	1246.15
6	1194.72	1246.01
7	1353.14	1306.46
8	1354.41	1308.01
9	1355.66	1309.57
10	1356.66	1311.31
11	1356.77	1312.00

** Corrected JANBU FOS = 1.996 ** (Fo factor = 1.014)

Failure surface No. 6 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1186.51	1248.25
2	1187.63	1247.18
3	1189.26	1246.02
4	1190.95	1244.96
5	1192.58	1243.80
6	1194.03	1242.42
7	1195.66	1241.26
8	1353.95	1307.90
9	1355.21	1309.46
10	1356.10	1311.24
11	1356.70	1312.00

** Corrected JANBU FOS = 1.998 ** (Fo factor = 1.025)

Failure surface No. 7 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1191.22	1250.81
2	1192.53	1249.53
3	1193.95	1248.12
4	1195.89	1247.63
5	1197.50	1246.44
6	1346.43	1306.87
7	1347.38	1308.63
8	1348.74	1310.09
9	1350.08	1311.58
10	1350.50	1312.00

** Corrected JANBU FOS = 2.003 ** (Fo factor = 1.018)

Failure surface No. 8 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1170.26	1240.13
2	1171.45	1239.13
3	1173.44	1239.04
4	1175.04	1237.84

5	1176.54	1236.52
6	1178.54	1236.41
7	1180.42	1235.75
8	1349.49	1304.78
9	1350.20	1306.65
10	1351.55	1308.12
11	1352.18	1310.02
12	1353.59	1311.44
13	1353.86	1312.00

** Corrected JANBU FOS = 2.018 ** (Fo factor = 1.019)

Failure surface No. 9 specified by 12 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1155.57	1235.19
2	1156.92	1234.28
3	1158.38	1232.91
4	1160.09	1231.87
5	1161.52	1230.48
6	1163.09	1229.24
7	1164.82	1228.23
8	1357.34	1305.74
9	1358.19	1307.55
10	1358.79	1309.46
11	1359.48	1311.34
12	1360.05	1312.00

** Corrected JANBU FOS = 2.026 ** (Fo factor = 1.021)

Failure surface No.10 specified by 15 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1143.24	1231.08
2	1144.96	1230.91
3	1146.70	1229.93
4	1148.15	1228.54
5	1149.56	1227.13
6	1151.27	1226.09
7	1153.15	1225.40
8	1154.86	1224.38
9	1156.76	1223.75
10	1158.76	1223.65
11	1160.50	1222.67
12	1357.19	1307.65
13	1358.18	1309.39
14	1358.80	1311.29
15	1359.21	1312.00

** Corrected JANBU FOS = 2.030 ** (Fo factor = 1.028)

 **
 ** Out of the 750 surfaces generated and analyzed by XSTABL, **
 ** 68 surfaces were found to have MISLEADING FOS values. **
 **

The following is a summary of the TEN most critical surfaces

Problem Description : Section E-E' Parallel Bedding (mid)

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)
1.	1.899	1.015	1183.08	1342.97	2.187E+05
2.	1.942	1.020	1193.79	1355.79	2.349E+05
3.	1.946	1.020	1188.65	1350.63	2.482E+05
4.	1.975	1.023	1151.68	1349.92	3.049E+05

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	20.00	4000.0	28.00
2	24.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating sliding BLOCK surfaces, has been
specified.

750 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of
sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1160.0	1215.0	1220.0	1245.0	30.0
2	1290.0	1300.0	1360.0	1300.0	20.0

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1183.08	1246.54
2	1183.76	1246.10
3	1185.50	1245.11
4	1187.27	1244.19
5	1188.74	1242.83
6	1339.81	1306.75
7	1340.65	1308.56
8	1342.05	1309.99
9	1342.82	1311.83
10	1342.97	1312.00

** Corrected JANBU FOS = 1.369 ** (Fo factor = 1.015)

Failure surface No. 2 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1187.48	1248.74
2	1187.54	1248.69
3	1189.18	1247.54
4	1191.18	1247.41
5	1192.73	1246.15

6	1194.72	1246.01
7	1353.14	1306.46
8	1354.41	1308.01
9	1355.66	1309.57
10	1356.66	1311.31
11	1356.77	1312.00

** Corrected JANBU FOS = 1.390 ** (Fo factor = 1.014)

Failure surface No. 3 specified by 9 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1193.79	1252.53
2	1194.45	1252.14
3	1196.18	1251.14
4	1197.69	1249.83
5	1199.24	1248.57
6	1200.69	1247.19
7	1354.30	1309.71
8	1355.39	1311.39
9	1355.79	1312.00

** Corrected JANBU FOS = 1.408 ** (Fo factor = 1.020)

Failure surface No. 4 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1188.65	1249.33
2	1189.36	1248.62
3	1191.36	1248.53
4	1193.35	1248.39
5	1195.10	1247.43
6	1196.63	1246.14
7	1198.21	1244.91
8	1347.49	1308.46
9	1348.71	1310.04
10	1350.11	1311.47
11	1350.63	1312.00

** Corrected JANBU FOS = 1.416 ** (Fo factor = 1.020)

Failure surface No. 5 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1170.26	1240.13
2	1171.45	1239.13
3	1173.44	1239.04
4	1175.04	1237.84
5	1176.54	1236.52
6	1178.54	1236.41

1 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pore Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	7.00	4000.0	28.00
2	13.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

500 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 4.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1200.0	1245.0	1240.0	1274.0	20.0
2	1340.0	1301.0	1420.0	1301.0	20.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

** Factor of safety calculation for surface # 18 **
** failed to converge within FIFTY iterations **
** **
** The last calculated value of the FOS was 14.9519 **
** This will be ignored for final summary of results **

The trial failure surface in question is
defined by the following 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1234.38	1280.07
2	1236.81	1278.49

```

The trial failure surface in question is defined by the following 8 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1237.67	1282.37
2	1239.81	1280.99
3	1408.63	1295.72
4	1410.81	1299.08
5	1412.99	1302.43
6	1415.17	1305.79
7	1417.34	1309.14
8	1419.20	1312.00

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1218.08	1268.72
2	1218.78	1268.26
3	1408.65	1310.99
4	1409.31	1312.00

** Corrected JANBU FOS = 2.510 ** (Fo factor = 1.002)

Failure surface No. 2 specified by 4 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1227.32	1275.13
2	1229.32	1273.83
3	1402.03	1310.87
4	1402.76	1312.00

** Corrected JANBU FOS = 2.855 ** (Fo factor = 1.005)

Failure surface No. 3 specified by 6 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1209.97	1263.31
2	1211.81	1262.12
3	1400.49	1304.67
4	1402.67	1308.02
5	1404.85	1311.38
6	1405.25	1312.00

** Corrected JANBU FOS = 2.876 ** (Fo factor = 1.014)

Failure surface No. 4 specified by 6 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1208.78	1262.52
2	1211.16	1260.98
3	1396.51	1303.34
4	1398.69	1306.70
5	1400.87	1310.05
6	1402.14	1312.00

** Corrected JANBU FOS = 2.922 ** (Fo factor = 1.017)

Failure surface No. 5 specified by 9 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1195.66	1253.77
2	1198.07	1252.21
3	1201.42	1250.04
4	1416.00	1298.08
5	1418.18	1301.44
6	1420.36	1304.79
7	1422.54	1308.15
8	1424.72	1311.50
9	1425.04	1312.00

** Corrected JANBU FOS = 3.010 ** (Fo factor = 1.022)

Failure surface No. 6 specified by 6 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1216.09	1267.39
2	1219.23	1265.35
3	1222.59	1263.17
4	1413.74	1306.94
5	1415.92	1310.30
6	1417.03	1312.00

** Corrected JANBU FOS = 3.037 ** (Fo factor = 1.013)

Failure surface No. 7 specified by 7 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1207.00	1261.33
2	1208.60	1260.30
3	1211.95	1258.12
4	1407.43	1302.24
5	1409.61	1305.59
6	1411.79	1308.95
7	1413.77	1312.00

** Corrected JANBU FOS = 3.040 ** (Fo factor = 1.018)

Failure surface No. 8 specified by 8 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1205.81	1260.54

2	1207.94	1259.16
3	1211.30	1256.98
4	1403.46	1300.91
5	1405.64	1304.26
6	1407.81	1307.62
7	1409.99	1310.97
8	1410.66	1312.00

** Corrected JANBU FOS = 3.067 ** (Fo factor = 1.020)

Failure surface No. 9 specified by 12 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1190.08	1250.05
2	1190.19	1249.98
3	1193.55	1247.80
4	1196.90	1245.62
5	1200.26	1243.45
6	1412.35	1292.00
7	1414.53	1295.36
8	1416.70	1298.71
9	1418.88	1302.07
10	1421.06	1305.42
11	1423.24	1308.78
12	1425.33	1312.00

** Corrected JANBU FOS = 3.126 ** (Fo factor = 1.030)

Failure surface No.10 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1221.37	1270.96
2	1222.18	1270.43
3	1399.45	1306.69
4	1401.63	1310.04
5	1402.90	1312.00

** Corrected JANBU FOS = 3.131 ** (Fo factor = 1.011)

 **
 ** Out of the 500 surfaces generated and analyzed by XSTABL, **
 ** 4 surfaces were found to have MISLEADING FOS values. **
 **

The following is a summary of the TEN most critical surfaces

Problem Description : Section E-E' Top 13-deg Bedding

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)
1.	2.510	1.002	1218.08	1409.31	1.903E+05

 ISOTROPIC Soil Parameters

1 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS

specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-40.00	4000.0	28.00
2	.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1100.0 ft and x = 1150.0 ft

Each surface terminates between x = 1160.0 ft and x = 1250.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

12.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS

specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-40.00	4000.0	28.00
2	.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced
along the ground surface between x = 1100.0 ft
and x = 1150.0 ft

Each surface terminates between x = 1265.0 ft
and x = 1300.0 ft

Unless further limitations were imposed, the minimum elevation
at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

12.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such

cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 5 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1068.60	1175.72
2	1069.50	1174.84
3	1072.84	1172.64
4	1272.92	1255.92
5	1267.21	1250.20

** Corrected JANBU FOS = 1.408 ** (Fo factor = 1.010)

Failure surface No. 2 specified by 8 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
-----------	-------------	-------------

1	1055.03	1170.64
2	1055.81	1169.93
3	1058.67	1167.14
4	1062.67	1167.05
5	1279.65	1271.18
6	1282.42	1274.06
7	1284.92	1277.19
8	1287.31	1280.00

** Corrected JANBU FOS = 1.673 ** (Fo factor = 1.012)

Failure surface No. 3 specified by 8 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1063.07	1173.65
2	1064.52	1172.22
3	1068.40	1171.24
4	1272.33	1268.84
5	1275.07	1271.76
6	1277.64	1274.82
7	1279.63	1278.29
8	1280.02	1280.00

** Corrected JANBU FOS = 1.688 ** (Fo factor = 1.013)

Failure surface No. 4 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1067.94	1175.48
2	1069.05	1174.74
3	1072.51	1172.73
4	1075.61	1170.21
5	1276.58	1262.14
6	1279.31	1265.06
7	1281.29	1268.54
8	1283.76	1271.68
9	1286.52	1274.58
10	1289.05	1277.68
11	1291.27	1280.00

** Corrected JANBU FOS = 1.790 ** (Fo factor = 1.019)

Failure surface No. 5 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1050.82	1169.06
2	1053.27	1167.62
3	1057.11	1166.52
4	1060.36	1164.18
5	1271.50	1264.67
6	1274.08	1267.73
7	1276.36	1271.01
8	1279.05	1273.98
9	1280.53	1277.70
10	1281.23	1280.00

** Corrected JANBU FOS = 1.814 ** (Fo factor = 1.018)

Failure surface No. 6 specified by 10 coordinate points

Point	x-surf	y-surf
-------	--------	--------

No.	(ft)	(ft)
1	1070.08	1176.28
2	1070.29	1176.12
3	1074.11	1174.95
4	1076.95	1172.14
5	1275.63	1264.08
6	1278.23	1267.11
7	1279.48	1270.91
8	1280.39	1274.81
9	1282.78	1278.01
10	1284.55	1280.00

** Corrected JANBU FOS = 1.823 ** (Fo factor = 1.021)

Failure surface No. 7 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1062.41	1173.40
2	1062.45	1173.37
3	1065.30	1170.57
4	1271.77	1257.37
5	1274.34	1260.44
6	1274.98	1264.39
7	1277.32	1267.63
8	1279.30	1271.10
9	1280.91	1274.76
10	1249.84	1243.69

** Corrected JANBU FOS = 1.827 ** (Fo factor = 1.009)

Failure surface No. 8 specified by 11 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1072.67	1177.25
2	1074.14	1176.02
3	1077.84	1174.50
4	1268.17	1260.10
5	1270.19	1263.55
6	1272.77	1266.61
7	1275.34	1269.67
8	1278.12	1272.55
9	1280.85	1275.48
10	1282.33	1279.19
11	1282.61	1280.00

** Corrected JANBU FOS = 1.845 ** (Fo factor = 1.023)

Failure surface No. 9 specified by 13 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1061.14	1172.93
2	1064.71	1172.17
3	1067.63	1169.44
4	1071.63	1169.26
5	1074.82	1166.84
6	1078.41	1165.07
7	1279.53	1261.88
8	1281.76	1265.20
9	1283.91	1268.57
10	1286.66	1271.48
11	1288.77	1274.87

12	1291.02	1278.18
13	1291.60	1280.00

** Corrected JANBU FOS = 1.849 ** (Fo factor = 1.026)

Failure surface No.10 specified by 10 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1060.33	1172.62
2	1061.44	1171.71
3	1065.44	1171.56
4	1069.44	1171.54
5	1264.59	1264.61
6	1266.68	1268.02
7	1267.88	1271.84
8	1270.67	1274.70
9	1272.91	1278.01
10	1273.99	1280.00

** Corrected JANBU FOS = 1.861 ** (Fo factor = 1.019)

 **
 ** Out of the 1000 surfaces generated and analyzed by XSTABL, **
 ** 36 surfaces were found to have MISLEADING FOS values. **
 **

The following is a summary of the TEN most critical surfaces

Problem Description : Section G-G' Parallel Slope

	Modified JANBU FOS	Correction Factor	Initial x-coord (ft)	Terminal x-coord (ft)	Available Strength (lb)
1.	1.408	1.010	1068.60	1267.21	3.107E+05
2.	1.673	1.012	1055.03	1287.31	3.223E+05
3.	1.688	1.013	1063.07	1280.02	2.869E+05
4.	1.790	1.019	1067.94	1291.27	4.142E+05
5.	1.814	1.018	1050.82	1281.23	3.700E+05
6.	1.823	1.021	1070.08	1284.55	3.627E+05
7.	1.827	1.009	1062.41	1249.84	3.582E+05
8.	1.845	1.023	1072.67	1282.61	3.612E+05
9.	1.849	1.026	1061.14	1291.60	5.058E+05
10.	1.861	1.019	1060.33	1273.99	3.107E+05

A Critical Failure Surface Searching Method, Using A Random Technique For Generating Circular Surfaces, Has Been Specified.

625 Trial Surfaces Have Been Generated.

25 Surfaces Initiate From Each Of 25 Points Equally Spaced Along The Ground Surface Between X = 51.00 ft.
and X = 230.00 ft.

Each Surface Terminates Between X = 265.00 ft.
and X = 440.00 ft.

Unless Further Limitations Were Imposed, The Minimum Elevation
At Which A Surface Extends Is $Y = .00$ ft.

12.00 ft. Line Segments Define Each Trial Failure Surface.

Following Are Displayed The Ten Most Critical Of The Trial
Failure Surfaces Examined. They Are Ordered - Most Critical
First.

* * Safety Factors Are Calculated By The Modified Bishop Method * *

Problem Description : Section G-G

 SEGMENT BOUNDARY COORDINATES

13 SURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	1000.0	1255.0	1030.0	1240.0	1
2	1030.0	1240.0	1060.0	1190.0	1
3	1060.0	1190.0	1080.0	1170.0	1
4	1080.0	1170.0	1100.0	1160.0	1
5	1100.0	1160.0	1130.0	1170.0	1
6	1130.0	1170.0	1200.0	1185.0	1
7	1200.0	1185.0	1280.0	1225.0	1
8	1280.0	1225.0	1310.0	1280.0	2
9	1310.0	1280.0	1360.0	1280.0	2
10	1360.0	1280.0	1400.0	1280.0	1
11	1400.0	1280.0	1420.0	1290.0	1
12	1420.0	1290.0	1615.0	1290.0	1
13	1615.0	1290.0	1650.0	1310.0	1

2 SUBSURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	1280.0	1225.0	1330.0	1225.0	2
2	1330.0	1225.0	1360.0	1280.0	2

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight (pcf)	Moist Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0
2	120.0	130.0	120.0	33.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	27.00	4000.0	28.00
2	31.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

100 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1220.0	1155.0	1240.0	1165.0	20.0
2	1325.0	1215.0	1340.0	1215.0	10.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 56 coordinate points

2 SUBSURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	1280.0	1225.0	1330.0	1225.0	2
2	1330.0	1225.0	1360.0	1280.0	2

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0
2	120.0	130.0	120.0	33.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	27.00	4000.0	28.00
2	31.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
 of .150 has been assigned

A vertical earthquake loading coefficient
 of .000 has been assigned

A critical failure surface searching method, using a random
 technique for generating sliding BLOCK surfaces, has been
 specified.

The active and passive portions of the sliding surfaces
 are generated according to the Rankine theory.

100 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of
 sliding block is 2.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1220.0	1155.0	1240.0	1165.0	20.0
2	1325.0	1215.0	1340.0	1215.0	10.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight (pcf)	Moist Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	120.0	33.00	.000	.0	0
2	120.0	130.0	4000.0	28.00	.000	.0	0

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1010.0 ft and x = 1120.0 ft

Each surface terminates between x = 1230.0 ft and x = 1310.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

13.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -15.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
is specified by 23 coordinate points

ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pore Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	120.0	33.00	.000	.0	0
2	120.0	130.0	4000.0	28.00	.000	.0	0

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1010.0 ft and x = 1120.0 ft

Each surface terminates between x = 1230.0 ft and x = 1310.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

13.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -15.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self

weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface is specified by 23 coordinate points

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1320.0 ft and x = 1380.0 ft

Each surface terminates between x = 1450.0 ft and x = 1520.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

7.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -15.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
is specified by 21 coordinate points

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 2 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	.00	4000.0	28.00
2	20.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1050.0 ft and x = 1100.0 ft

Each surface terminates between x = 1170.0 ft and x = 1250.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

8.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
 Upper angular limit := (slope angle - 5.0) degrees

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
 is specified by 18 coordinate points

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1050.0 ft and x = 1100.0 ft

Each surface terminates between x = 1170.0 ft and x = 1250.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

8.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined

within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	.00	4000.0	28.00
2	20.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1320.0 ft and x = 1370.0 ft

Each surface terminates between x = 1375.0 ft and x = 1500.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

4.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
 Upper angular limit := (slope angle - 5.0) degrees

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Moist (pcf)	Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	120.0	33.00	.000	.0	0
2	120.0	130.0	4000.0	28.00	.000	.0	0

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1040.0 ft and x = 1200.0 ft

Each surface terminates between x = 1300.0 ft and x = 1500.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

27.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface is specified by 21 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1048.42	1181.90

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1 Soil Unit(s)

Soil Unit 2 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	.00	1000.0	33.00
2	20.00	150.0	24.00
3	90.00	1000.0	33.00

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

200 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 3.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1115.0	1227.0	1180.0	1260.0	30.0
2	1350.0	1320.0	1460.0	1325.0	30.0

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 35 coordinate points

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced
along the ground surface between x = 1040.0 ft
and x = 1250.0 ft

Each surface terminates between x = 1260.0 ft
and x = 1560.0 ft

Unless further limitations were imposed, the minimum elevation
at which a surface extends is y = 1100.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

27.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

** Factor of safety calculation for surface # 323 **
** failed to converge within FIFTY iterations **
** **
** The last calculated value of the FOS was .0038 **
** This will be ignored for final summary of results **

Circular surface (FOS= .0038) is defined by: xcenter = 1048.27
ycenter = 1509.38 Init. Pt. = 1216.84 Seg. Length = 27.00

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
is specified by 22 coordinate points

Problem Description : Section M2-M2' 2:1 Backcut

 SEGMENT BOUNDARY COORDINATES

5 SURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	.0	1390.0	30.0	1385.0	2
2	30.0	1385.0	55.0	1378.0	2
3	55.0	1378.0	68.0	1382.0	1
4	68.0	1382.0	126.0	1440.0	1
5	126.0	1440.0	240.0	1440.0	1

6 SUBSURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	55.0	1378.0	80.0	1358.0	2
2	80.0	1358.0	90.0	1358.0	2
3	90.0	1358.0	110.0	1380.0	2
4	110.0	1380.0	128.0	1380.0	2
5	128.0	1380.0	178.0	1405.0	2
6	178.0	1405.0	240.0	1420.0	2

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pore Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	120.0	33.00	.000	.0	0
2	120.0	130.0	150.0	24.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 2 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	47.00	4000.0	28.00
2	53.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

400 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 10.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	100.0	1340.0	120.0	1360.0	20.0

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 16 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	60.05	1379.55
2	66.85	1375.86
3	75.64	1371.08
4	84.43	1366.31
5	93.22	1361.54
6	100.72	1356.67
7	109.10	1351.22
8	134.64	1380.05
9	137.78	1384.89
10	142.55	1393.68
11	147.32	1402.47
12	152.09	1411.25

13	156.87	1420.04
14	161.64	1428.83
15	166.41	1437.62
16	167.70	1440.00

** Corrected JANBU FOS = 2.360 ** (Fo factor = 1.088)

Failure surface No. 2 specified by 18 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	52.57	1378.68
2	57.48	1376.01
3	63.85	1372.55
4	72.64	1367.78
5	81.43	1363.01
6	90.22	1358.24
7	91.45	1357.44
8	99.84	1351.99
9	108.23	1346.54
10	140.58	1384.81
11	142.00	1387.00
12	146.77	1395.79
13	151.55	1404.58
14	156.32	1413.37
15	161.09	1422.15
16	165.86	1430.94
17	170.63	1439.73
18	170.78	1440.00

** Corrected JANBU FOS = 2.379 ** (Fo factor = 1.088)

Failure surface No. 3 specified by 16 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	59.71	1379.45
2	66.68	1375.66
3	75.47	1370.89
4	84.26	1366.12
5	93.04	1361.35
6	99.99	1356.84
7	108.37	1351.39
8	129.37	1376.21
9	133.67	1382.84
10	138.44	1391.62
11	143.21	1400.41
12	147.99	1409.20
13	152.76	1417.99
14	157.53	1426.78
15	162.30	1435.56

5	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1150.0 ft
 and x = 1220.0 ft

Each surface terminates between x = 1330.0 ft
 and x = 1410.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1450.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

10.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -55.0 degrees
 Upper angular limit := (slope angle - 5.0) degrees

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter.. In such

cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

A horizontal earthquake loading coefficient
 of .150 has been assigned

A vertical earthquake loading coefficient
 of .000 has been assigned

A critical failure surface searching method, using a random
 technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced
 along the ground surface between x = 1150.0 ft
 and x = 1220.0 ft

Each surface terminates between x = 1330.0 ft
 and x = 1410.0 ft

Unless further limitations were imposed, the minimum elevation
 at which a surface extends is y = 1450.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

10.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
 within the angular range defined by :

Lower angular limit := -55.0 degrees
 Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1255.0 ft and x = 1330.0 ft

Each surface terminates between x = 1340.0 ft and x = 1460.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1450.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

7.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -55.0 degrees
 Upper angular limit := (slope angle - 5.0) degrees

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such

cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

17	1280.00	28.15	3356.	2.82	13.00	.217
18	1290.00	.00	-3.	3.08	3.00	1.027

 AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 1233.06 (psf)
 Pore Water Pressure = .00 (psf)
 Shear Stress = 640.56 (psf)

Total Length of failure surface = 205.38 feet

 For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = .981

Total shear strength available
 along specified failure surface = 129.04E+03 lb

Section P-P
10 most critical surfaces, MINIMUM BISHOP FOS = 1.666

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 5

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-80.00	4000.0	28.00
2	-45.00	150.0	24.00
3	10.00	4000.0	28.00
4	60.00	150.0	24.00
5	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

2500 trial surfaces will be generated and analyzed.

50 Surfaces initiate from each of 50 points equally spaced along the ground surface between x = 1220.0 ft and x = 1280.0 ft

Each surface terminates between x = 1300.0 ft and x = 1380.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = .0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

6.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface is specified by 24 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1244.49	1512.24

2	1250.45	1512.93

5	1240.0	1510.0	1400.0	1510.0	1

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Water Surface Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0
2	120.0	130.0	120.0	33.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 5

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-80.00	4000.0	28.00
2	-45.00	150.0	24.00
3	10.00	4000.0	28.00
4	60.00	150.0	24.00
5	90.00	4000.0	28.00

A horizontal earthquake loading coefficient
of .150 has been assigned

A vertical earthquake loading coefficient
of .000 has been assigned

A critical failure surface searching method, using a random
technique for generating CIRCULAR surfaces has been specified.

2500 trial surfaces will be generated and analyzed.

50 Surfaces initiate from each of 50 points equally spaced
along the ground surface between x = 1220.0 ft
and x = 1280.0 ft

Each surface terminates between x = 1300.0 ft
and x = 1380.0 ft

Unless further limitations were imposed, the minimum elevation
at which a surface extends is y = .0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

6.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such

cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
 is specified by 26 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	1242.04	1511.02
2	1248.03	1511.35
3	1254.01	1511.87

6	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

900 trial surfaces will be generated and analyzed.

30 Surfaces initiate from each of 30 points equally spaced along the ground surface between x = 220.0 ft and x = 270.0 ft

Each surface terminates between x = 390.0 ft and x = 425.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1450.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

10.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED BISHOP METHOD * * * * *

The most critical circular failure surface
 is specified by 19 coordinate points

Point No.	x-surf (ft)	y-surf (ft)
1	270.00	1484.00
2	279.96	1484.89
3	289.86	1486.32

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	ϕ -value (degrees)
1	15.00	4000.0	28.00
2	21.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating sliding BLOCK surfaces, has been specified.

The active and passive portions of the sliding surfaces are generated according to the Rankine theory.

400 trial surfaces will be generated and analyzed.

2 boxes specified for generation of central block base

Length of line segments for active and passive portions of sliding block is 10.0 ft

Box no.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Width (ft)
1	1140.0	1235.0	1160.0	1255.0	1.0
2	1240.0	1278.0	1330.0	1284.0	22.0

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

Section U - U' Parallel Bedd
10 most critical surfaces, MINIMUM JANBU FOS = 1.467

Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

 USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1300.0 ft and x = 1450.0 ft

Each surface terminates between x = 1750.0 ft and x = 1900.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = 1000.0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

29.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

```
*****
-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)
*****
Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.
*****
```

USER SELECTED option to maintain strength greater than zero

4	1230.00	26.87	5503.	15.76	20.31	.776
5	1290.66	26.87	-8680.	1.03	2.92	.352
6	1292.65	.00	-13.	.03	.00	.000

 AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 1692.16 (psf)
 Pore Water Pressure = .00 (psf)
 Shear Stress = 686.50 (psf)

Total Length of failure surface = 164.48 feet

 For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = 1.586

Total shear strength available along specified failure surface = 179.04E+03 lb

 For the specified surface, the analysis computed the following:

Negative (tensile) Normal Effective Force = 0 slices
 Negative (tensile) Interslice Force = 1 slices
 Unreasonable Location of Interslice Force = 0 slices

In view of these errors, the computed FOS may be UNREASONABLE!

Section W-W landslide Removed
10 most critical surfaces, MINIMUM JANBU FOS = 1.633

 -- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

 Negative effective stresses were calculated at the base of a slice.
 This warning is usually reported for cases where slices have low self
 weight and a relatively high "c" shear strength parameter. In such
 cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

 AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 2422.84 (psf)
 Pore Water Pressure = .00 (psf)
 Shear Stress = 1076.20 (psf)

Total Length of failure surface = 280.37 feet

 For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = 1.342

Total shear strength available
 along specified failure surface = 404.79E+03 lb

 For the specified surface, the analysis computed the following:

Negative (tensile) Normal Effective Force = 0 slices
 Negative (tensile) Interslice Force = 1 slices
 Unreasonable Location of Interslice Force = 0 slices

In view of these errors, the computed FOS may be UNREASONABLE!

6	1326.06	.00	0.	-.14	.00	.000

AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 2215.56 (psf)
Pore Water Pressure = .00 (psf)
Shear Stress = 976.39 (psf)

Total Length of failure surface = 221.04 feet

For the single specified surface and the assumed angle of the interslice forces, the SPENCER'S (1973) procedure gives a

FACTOR OF SAFETY = 1.255

Total shear strength available along specified failure surface = 270.80E+03 lb

For the specified surface, the analysis computed the following:

Negative (tensile) Normal Effective Force = 0 slices
Negative (tensile) Interslice Force = 1 slices
Unreasonable Location of Interslice Force = 0 slices

In view of these errors, the computed FOS may be UNREASONABLE!

Section X-X Static Case
10 most critical surfaces, MINIMUM JANBU FOS = 2.803

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1 Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-56.00	4000.0	28.00
2	-54.00	150.0	24.00
3	90.00	4000.0	28.00

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

600 trial surfaces will be generated and analyzed.

30 Surfaces initiate from each of 20 points equally spaced along the ground surface between x = 1500.0 ft
 and x = 1700.0 ft

Each surface terminates between x = 1960.0 ft
 and x = 2160.0 ft

Unless further limitations were imposed, the minimum elevation at which a surface extends is y = .0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

21.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice. This warning is usually reported for cases where slices have low self weight and a relatively high "c" shear strength parameter. In such cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

* * * * * SIMPLIFIED JANBU METHOD * * * * *

The 10 most critical of all the failure surfaces examined are displayed below - the most critical first

Failure surface No. 1 specified by 27 coordinate points

Point No.	x-surf (ft)	y-surf (ft)

Problem Description : Section X-X Pseudostatic Case

SEGMENT BOUNDARY COORDINATES

18 SURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	990.0	1200.0	1055.0	1190.0	1
2	1055.0	1190.0	1150.0	1245.0	1
3	1150.0	1245.0	1270.0	1220.0	1
4	1270.0	1220.0	1420.0	1235.0	1
5	1420.0	1235.0	1570.0	1280.0	1
6	1570.0	1280.0	1600.0	1290.0	1
7	1600.0	1290.0	1620.0	1300.0	1
8	1620.0	1300.0	1640.0	1320.0	1
9	1640.0	1320.0	1710.0	1360.0	1
10	1710.0	1360.0	1760.0	1360.0	1
11	1760.0	1360.0	1820.0	1400.0	1
12	1820.0	1400.0	1850.0	1420.0	2
13	1850.0	1420.0	1860.0	1420.0	2
14	1860.0	1420.0	1910.0	1450.0	2
15	1910.0	1450.0	1920.0	1450.0	2
16	1920.0	1450.0	1940.0	1460.0	2
17	1940.0	1460.0	2030.0	1460.0	2
18	2030.0	1460.0	2370.0	1470.0	1

4 SUBSURFACE boundary segments

Segment No.	x-left (ft)	y-left (ft)	x-right (ft)	y-right (ft)	Soil Unit Below Segment
1	1820.0	1400.0	1900.0	1420.0	1
2	1900.0	1420.0	1925.0	1420.0	1
3	1925.0	1420.0	1960.0	1435.0	1
4	1960.0	1435.0	2030.0	1460.0	1

 ISOTROPIC Soil Parameters

2 Soil unit(s) specified

Soil Unit No.	Unit Weight Moist (pcf)	Unit Weight Sat. (pcf)	Cohesion Intercept (psf)	Friction Angle (deg)	Pore Pressure Parameter Ru	Pore Pressure Constant (psf)	Water Surface No.
1	120.0	130.0	150.0	24.00	.000	.0	0
2	120.0	130.0	120.0	33.00	.000	.0	0

 ANISOTROPIC STRENGTH PARAMETERS
 specified for 1 Soil Unit(s)

Soil Unit 1 is ANISOTROPIC

Number of direction ranges specified = 3

Direction Range No.	Counterclockwise Direction Limit (deg)	c-value (psf)	i-value (degrees)
1	-56.00	4000.0	28.00
2	-54.00	150.0	24.00
3	90.00	4000.0	28.00

A horizontal earthquake loading coefficient of .150 has been assigned

A vertical earthquake loading coefficient of .000 has been assigned

 A SINGLE FAILURE SURFACE HAS BEEN SPECIFIED FOR ANALYSIS

Trial failure surface specified by the following 27 coordinate points :

Point No.	x-surf (ft)	y-surf (ft)
1	1531.58	1268.47
2	1551.27	1261.17
3	1571.37	1255.11
4	1591.82	1250.31
5	1612.52	1246.80

6	1633.41	1244.59
7	1654.39	1243.69
8	1675.38	1244.10
9	1696.31	1245.82
10	1717.09	1248.84
11	1737.65	1253.15
12	1757.89	1258.74
13	1777.74	1265.58
14	1797.13	1273.65
15	1815.98	1282.91
16	1834.21	1293.33
17	1851.76	1304.87
18	1868.55	1317.48
19	1884.52	1331.11
20	1899.61	1345.72
21	1913.76	1361.23
22	1926.91	1377.61
23	1939.02	1394.77
24	1950.03	1412.65
25	1959.90	1431.18
26	1968.60	1450.30
27	1972.30	1460.00

 SELECTED METHOD OF ANALYSIS: Spencer (1973)

 SUMMARY OF INDIVIDUAL SLICE INFORMATION

Slice	x-base (ft)	y-base (ft)	height (ft)	width (ft)	alpha	beta	weight (lb)

AVERAGE VALUES ALONG FAILURE SURFACE

Total Normal Stress = 7605.24 (psf)
Pore Water Pressure = .00 (psf)
Shear Stress = 3633.49 (psf)

Total Length of failure surface = 535.38 feet

For the single specified surface and the assumed angle
of the interslice forces, the SPENCER'S (1973)
procedure gives a

FACTOR OF SAFETY = 2.162

Total shear strength available
along specified failure surface = 420.55E+04 lb

For the specified surface, the analysis computed the following:

Negative (tensile) Normal Effective Force = 1 slices
Negative (tensile) Interslice Force = 0 slices
Unreasonable Location of Interslice Force = 0 slices

In view of these errors, the computed FOS may be UNREASONABLE!

Section Y-Y' circular
10 most critical surfaces, MINIMUM BISHOP FOS = 1.979

A critical failure surface searching method, using a random technique for generating CIRCULAR surfaces has been specified.

400 trial surfaces will be generated and analyzed.

20 Surfaces initiate from each of 20 points equally spaced
along the ground surface between x = 40.0 ft
and x = 80.0 ft

Each surface terminates between x = 120.0 ft
and x = 180.0 ft

Unless further limitations were imposed, the minimum elevation
at which a surface extends is y = .0 ft

* * * * * DEFAULT SEGMENT LENGTH SELECTED BY XSTABL * * * * *

4.0 ft line segments define each trial failure surface.

ANGULAR RESTRICTIONS :

The first segment of each failure surface will be inclined
within the angular range defined by :

Lower angular limit := -45.0 degrees
Upper angular limit := (slope angle - 5.0) degrees

-- WARNING -- WARNING -- WARNING -- WARNING -- (# 48)

Negative effective stresses were calculated at the base of a slice.
This warning is usually reported for cases where slices have low self
weight and a relatively high "c" shear strength parameter. In such
cases, this effect can only be eliminated by reducing the "c" value.

USER SELECTED option to maintain strength greater than zero

Factors of safety have been calculated by the :

**Subject: Preliminary Geotechnical Investigation
Chatsworth Ridge Estates Project, Tentative Tract No. 53138
Chatsworth Area, Los Angeles County, California**

Dear Mr. Garlinghouse:

Kleinfelder, Inc. is pleased to present this preliminary geotechnical investigation report for Presidio Chatsworth Partners, LLC conducted for the proposed Chatsworth Ridge Estates residential development project, Tentative Tract No. 53138, located in the Chatsworth area of Los Angeles County, California. This investigation report, in part, addresses comments contained in the Geologic and Soil Engineering review sheets prepared by Los Angeles County, Department of Public Works, dated March 21, 2001 and July 9, 2001. The results of our combined geologic and geotechnical investigation, along with our conclusions, and recommendations for preliminary design of the project, are presented in the attached report.

In general, the site is, in our opinion, considered suitable for the proposed residential development from both a geologic and geotechnical perspective, provided the recommendations contained herein are properly incorporated into the planning, design, and construction of the project. Although the site is situated in the general vicinity of the 1994 Northridge Earthquake, preliminary studies at the site indicate that evidence of active surface faulting was not observed on site. Seismic design of structures will require incorporation of UBC (1997) seismic design criteria. Compressible soils and/or liquefiable soils appear to be confined to near-surface soil deposits and in the drainages where development is not proposed. Three mapped landslides and several areas of surficial instability were identified along Browns and Devils Canyons where steeper slopes occur. Recommendations for avoidance or mitigation alternatives are included in this report.

We appreciate the opportunity to be of service to Presidio Chatsworth Partners on this project. If you have any questions, comments, or require additional information, please do not hesitate to contact our office.

Respectfully submitted,

KLEINFELDER, INC.

1 INTRODUCTION

This preliminary geotechnical investigation report has been prepared for Tentative Tract No. 53138, a 230-acre site proposed as a residential subdivision of 485 single family lots, 32 open space lots, 7 private "not a part" lots, and two bridges, located in the Chatsworth area of Los Angeles County, California. This investigation report addresses comments contained in the Geologic and Soil Engineering review sheets prepared by Los Angeles County, Department of Public Works, dated July 2001 (attached as Appendix G). The purpose of this report is to describe the geologic and geotechnical conditions of the site, to recommend applicable design and construction constraints, to evaluate potential geotechnical impacts on the project, and to recommend appropriate mitigation measures relative to the planned subdivision. Our scope of services included geologic mapping, review of select technical literature and aerial photographs, subsurface exploration, laboratory testing of select soil and rock samples, engineering analysis, and preparation of this written report.

1.1 PROPOSED DEVELOPMENT

The proposed project consists of 485 single-family residential lots, 32 open space lots to be developed on the 230-acre site as depicted on the 100-scale Vesting Tentative Tract 53138 Map dated August 2, 2001 by B & E Engineers of Arcadia, California. Preliminary earthwork estimates indicate that the site will be an approximately 2.2 million cubic yards cut/fill grading operation with the majority of the cuts being less than approximately 40 feet deep, and canyon fills of similar thickness. It is our understanding that the proposed earthwork approximately balances fill and cut quantities. The anticipated maximum depth of cut is approximately 100 feet deep, and the maximum depth of fill is approximately 80 feet. The highest fill slopes and cut slopes are 195 feet and 90 feet, respectively. Proposed graded slopes are planned at 2:1 (Horizontal : Vertical) or flatter finished grades.

Two bridges across Devil Canyon are proposed as a part of the project. One bridge is located where the main entrance road extends northeasterly from Topanga Canyon Boulevard crosses the canyon. The second bridge is located near the southeastern margin of the site where the northerly extension of Canoga Avenue crosses the canyon just downstream of the existing upper Twin Lakes dam. This investigation included a preliminary evaluation of the general vicinity of the proposed bridge abutment and approximate pier locations only. Future design-level studies will be required to assess these bridges in greater detail.

1.2 SITE DESCRIPTION

The 230-acre site is predominately located west of Brown's Canyon, on the south half of Section 6, Township 2 North, Range 16 West, northeast of the intersection of Topanga Canyon Blvd. and SR 118 (Simi Valley Freeway) in the Chatsworth area of Los Angeles County California. The approximately project boundaries relative to topographic landmarks are shown on the Site Location Map, Plate 1.

Generally, the site is bounded on the south by SR 118 and several single-family residences of the former Twin Lakes subdivision, and on the west, north, and east by undeveloped natural terrain. Several widely scattered single family residences exist on the project site and are remnant of the former Deer Lake Highlands subdivision. Presently, site access is available from the southwest via Topanga Canyon Boulevard and southeast from Canoga Avenue via existing, poorly to moderately maintained roads, most of which are unpaved.

Two intermittent drainage courses exists onsite including Devil Canyon which transects the site through the southwestern portion of the site. Browns Canyon forms a portion of the eastern property limit. Both are shown as blue line creeks on the USGS 7.5-Minute Oat Mountain Quadrangle Map that serves as the base for Plate 1. Streams in both of the canyons were observed to have seasonally flowing water. The topography of the site is partially controlled by these two drainages and their tributaries. Total relief across the site is approximately 400 feet. The maximum elevation at the site is approximately 1,540 feet at the northeast portion of the property and the minimum elevation is approximately 1,140 feet near the southeasterly portion of the site in Devil Canyon. Topographically, the site consists of rather rugged terrain with the deeply incised Devil and Browns Canyons. Easterly facing descending slopes along Browns Canyon range from 2:1 (H:V) to locally 1:1 (H:V).

The majority of canyon walls along Devil Canyon are steep; the topography of which is controlled by the underlying geologic structure. The north-facing slopes along the south side of the canyon are on the order of 2:1 and may be considered as dip slopes. The south-facing slopes along the north side of the canyon are somewhat steeper, on the order of 1:1(H:V) and are anti-dip (dipping into slope) slopes.

Within the northeasterly portion of the property above Devil Canyon, exists the former Deer Lake Highlands, an area of more subdued topography with moderate to gentle south-draining

slopes. Drainage is via well-defined natural drainage courses that direct runoff to the south and southeast into Devil Canyon, then into Browns Canyon.

Vegetation at the site varies from moderately wooded areas along tributaries and canyon bottoms to riparian vegetation, annual grasses, moderately dense Manzanita, and other low-growing, chaparral and shrubs existing throughout the site.

Existing improvements include several paved and unpaved roadways, abandoned building pads, five water wells (inclusive of one "oil" well), several existing residences, a small concrete/rock dam in Devil Canyon, and the former concrete lined "Deer Lake". Present access to the site is provided via several poorly to moderately maintained dirt roads. Other improvements include above-ground power lines, cisterns, ponds, and several other abandoned foundations.

1.3 SCOPE OF SERVICES

Our investigation for this tentative tract submittal included research, interpretation of aerial photographs, field geologic mapping, and field exploration over the period of November 20, 2000 through June 19, 2001. Subsurface exploration included drilling, sampling, and downhole geologic logging of 13 exploratory bucket auger borings, drilling, geologic logging and sampling of 6 exploratory continuous rock corings, excavation and logging of 31 exploration test pits, and two fault trenches. The subsurface exploration locations were severely constrained by site access limitations, stream crossings, and biologically sensitive areas.

Field exploration also included rock slope traverses and seismic refraction in exposed rock areas to assess Rock Mass Ratings and hardness relative to rippability potential. All Exploration locations are shown on Plates 13 and 14 and logs/data are provided along with a more detailed summary of subsurface exploration methods in Appendix A of this report.

The approximate location of field exploration points were located using the base map prepared by B&E Engineers and sighting and pacing from existing site improvements and topographic features. The exploration locations should be considered accurate only to the degree implied by this method.

Laboratory testing was performed on representative samples collected from explorations and were analyzed for soil and rock characteristics. The results of our analyses are included in Appendix B. Presentation of the test results provides only that information considered pertinent. References to ASTM and other test standards refer to the standard currently in effect.

2 ENGINEERING GEOLOGIC AND GEOTECHNICAL CONDITIONS

2.1 REGIONAL GEOLOGIC SETTING

The site is located in the western portion of Los Angeles County along the southern foothills of the Santa Susana Mountains of the Transverse Ranges geomorphic province (Plate 2). This province is characterized by west-northwest trending structure primarily the result of faulting and folding related to the compression of the region along the San Andreas Fault system. The Transverse Ranges are comprised by complex crystalline and sedimentary rock including Pre-Cambrian intrusions, Mesozoic plutonic, various metamorphic facies, and sedimentary rock.

The Santa Susana Mountains and related mountainous regions primarily consist of sedimentary rock and topographically define the boundary between the Los Angeles and Ventura Basins. Structurally, this region consists of a series of east-west trending faults and folds including the Iverson syncline, and Rocky Peak anticline, and faults such as the Northridge Hills, Red Mountain, San Cayetano, Oak Ridge, and Simi faults. Plate 3 shows the majority of these features with respect to the site.

2.2 HISTORIC SEISMICITY

The site is located in the seismically active southern California region (Plate 7). Major historic earthquakes felt in the vicinity of Chatsworth have usually originated from faults located outside the area. These include the 1857 Fort Tejon, 1925 Santa Barbara, 1933 Long Beach, 1952 Arvin-Tehachapi, 1971 San Fernando, 1987 Whittier Narrows, 1992 Landers, and 1994 Northridge earthquakes.

The MW 6.7 Northridge Earthquake occurred on January 17, 1994 and was located approximately 6 miles southeast of the proposed development site. This earthquake caused severe and widespread damage throughout southern California attributable to high intensity ground shaking and minor liquefaction. Mapping of ground rupture associated with this event was performed by the California Division of Mines and Geology (CDMG). This mapping effort concluded that surface deformation and cracking associated with the event was restricted to the Mission Wells, San Fernando, Veterans, and Hospital fault zones located a minimum of 3-1/2 miles east of the proposed project. Ground rupture was not observed along the Northridge Hills

fault that projects onto the subject site nor is the Northridge Hills fault considered to be related to this earthquake event.

2.3 EARTH MATERIALS

The site has been regionally mapped by several authors including Evans (1978), Diblee (1992), and Yerkes (1995). These geologic maps pertaining to the subject property are included herein as Plates 4, 5, and 6, respectively. The majority of the site is underlain by Chatsworth Formation; renamed from Evans' mapping as Chico Formation but of consistent lithology. The Saugus Formation forms younger surfaces along the northern boundary of the site. Each of these engineering geologic units are described (youngest to oldest) in the following sections.

2.3.1 Landslide (Map Symbol: Qls)

Landslides are mapped onsite on the basis of involvement in bedrock and an estimated thickness exceeding 10 feet. Three landslides were concluded to exist onsite: two along Devil's Canyon and one along the northern property boundary. Both of the slides along Devil's Canyon appear to be relatively shallow, translational, block-glide failures and occur on the dip-slope side of the canyon. The third appears to be considerably shallower and occurs along the formational contact between the Saugus and Chico Formations. These slides are differentiated from areas of shallower rock creep and/or surficial deposit failures throughout steeper portions of the site.

One bucket auger boring and two exploration trenches were excavated in another area suspected to be a landslide located along Browns Canyon. These excavations and surface mapping suggest that the area in question (vicinity of BA-1) is not a landslide. Trenching in the assumed headscarp area (TP-1 & TP-2) did not reveal any significant evidence of slippage. No evidence of typical landslide gouge was observed in BA-1, nor did the bedrock in the boring or trenches appear distorted or disturbed as compared to other on-site outcrops.

2.3.2 Alluvium (Map Symbol: Qal)

Alluvium is mapped along the bottoms of both Browns and Devil Canyons. These alluvial deposits occur along active stream channels where development is not proposed. These deposits are typically high in permeability, often compressible and/or liquefiable, and contain primarily clean sands, gravel, and localized boulders. This unit was mapped to include other low-density surficial deposits including colluvium, residual soils, and localized slope wash. The only

surficial deposit within the area of proposed development is the thin deposit of colluvium, consisting of poorly consolidated mixes of sand, silt, and gravel, which typically drapes the hillsides and flatter portions of the site.

2.3.3 Saugus Formation (Map Symbol: QTs)

The Saugus Formation consists of weakly consolidated, Plio-Pleistocene (i.e. 0.7 to 2.5 million years old) continental deposits. The Saugus Formation is mapped as isolated remnant outcrops on the northwest and northeast parts of the site and occurs throughout the terrain north of and adjacent to the northern property boundary. This earth unit generally consists of light gray to brown, pebble- to cobble-sized conglomerate supported by gray to red-brown sandstone to silty sandstone matrix. This unit can be characterized as a very soft to soft rock or dense soil. Clasts are generally sub-rounded to well-rounded and granitic, gneissic, metavolcanic, and gabbroic composition. This unit is poorly bedded to massive and generally relatively permeable. From a generalized engineering perspective, this unit rarely contains highly expansive soils, has moderate shear strength, and is relatively excavatable with typical earthwork equipment.

2.3.4 Chatsworth Formation (Map Symbol: Kcs)

Formerly mapped as the Chico Formations by Kew (1924) and Evans (1978), the Chatsworth Formation is a late Cretaceous (i.e. 65 to 135 million years old) marine sedimentary earth unit. It generally contains light gray to light brown, thick-bedded sandstone interbedded with thin layers siltstone and sandy shale. The rock is considered soft to moderately hard and moderately weathered. Bedding is typically well defined with many joints and fractures. The sandstone has moderate to high shear strength, with low permeabilities. Sandstone units are generally non-expansive with isolated beds of moderately expansive siltstone and claystone. Due to the hardness of the rock, difficulty in ripping and grading should be anticipated.

2.4 GROUNDWATER CONDITIONS

Surface water was observed onsite along Devil Canyon and adjacent Browns Canyon which are mapped as blue line streams on the USGS 7.5-Minute Quadrangle (Plate 1). A man-made pond was also observed near the northwest corner of the project and is described in a Phase I Site Assessment (PSA) for the project (Geosoils, 1999) as having existed since before 1928 and filled from a water well located approximately 100 feet to the north of the pond.

Five onsite water wells were identified in the Geosoils (1999) PSA report. One of the water wells was initially drilled as a speculative wild cat oil well and subsequently converted to a water well. No records for these wells were on file at Los Angeles County Hydrology Department. The depth of these wells could only be identified for one well at a depth of approximately 360 feet below ground surface (bgs). This depth suggests that the regional groundwater table is at that approximate depth and probably occurs within fractured sandstone of the Chatsworth Formation.

Shallow groundwater occurs onsite as a seasonal condition in localized areas, particularly along major tributaries such as Browns and Devil Canyons. Springs were observed along with phreatophytic (water-loving) vegetation along these canyons. The springs are probably seasonal releases of groundwater that percolates through fractures within the Chatsworth Formation. Proposed residential irrigation can be expected to increase local, seasonal groundwater levels. The influence of development is generally expected to have little to no influence on regional groundwater levels as hardscape will reduce infiltration and landscaping will increase recharge. However, localized seepage may be induced by earthwork such as where permeable (e.g. rocky) fill is placed over less permeable (e.g. rock) formations.

3 GEOLOGIC & GEOTECHNICAL FINDINGS

3.1 ONSITE FAULTING

The subject property is located adjacent to a number of west-trending Quaternary faults but none of which are mapped across the site. The site is not situated within any Earthquake Fault-Rupture Hazard Zone (Formerly A-P Zone) as currently designated by the State of California (Hart and Byrant, 2000). The nearest "A-P" Zone is that established for the San Cayetano fault located approximately 1.5 miles west of the site and the Verdugo fault located approximately 14 km east of the site. The nearest mapped Quaternary fault is the Northridge Hills Fault, as shown on Plate 3. Local, recent seismicity is shown on Plate 7. This seismicity is primarily the result of aftershock activity related to the 1994 M 6.7 Northridge earthquake. A considerable resurgence of fault studies occurred in response to the 1994 Northridge earthquake largely conducted by the CDMG under funding of the Fault Evaluation Report (FER) program. Renewed movement along the Northridge Hills fault was not observed by the CDMG following the 1994 Northridge earthquake and this fault remains unzoned. Plate 8 shows the CDMG mapping of faults concluded to have ground rupture in association with the 1994 event. These studies generally review existing data to determine the activity of faults in order to assess the need to establish Alquist-Priolo zones. These FER's concluded that the Northridge Hills (FER-52), Simi (FER-48), and Mission Hills, Devonshire, and related faults (FER-73) may have late Pleistocene displacement but no evidence for Holocene faulting was noted. The CDMG index map of FER's within the site vicinity is included as Plate 9.

Although the Northridge Hills fault is mapped as projecting onto the site, FER-52 concludes that:

"The Northridge Hills fault is most probably a late Quaternary fault along which some dip slip movement has occurred. It is most probable that the fault movement is up relatively on the north, and thus may be related to the San Fernando and/or Santa Susana faults, although such may be disputed. There is no available evidence to support or deny a strike slip component of faulting. Neither Holocene activity nor inactivity can be conclusively demonstrated."
(Smith 1977).

The conclusion that the Northridge Hills fault may be related to the active Santa Susana and/or San Fernando faults allows the interpretation that secondary displacement could be expected along the Northridge Hills and other potentially related faults. Secondary displacement is ground fracturing that occurs with some minor, associated displacement resulting from high intensity ground shaking that relieves minor accumulated stress along pre-existing zones of weakness (such as along older, pre-Holocene faults). Such ground surface expression is usually constrained to fracturing (i.e. no displacement) with possible isolated segments having very minor displacement.

Since a number of major folds, bedrock faults, and other questionable features are mapped on or adjacent and projecting toward the site, aerial photographs were reviewed and observed, possible fault-related lineaments were identified, as shown on Plate 10. During site mapping, both regionally mapped faults and identified photo-lineaments were further reviewed in the field. Evidence of recent ground rupture was not observed. Several folds have been mapped adjacent to and projecting onto the site. These folds are believed to be the result of pre-Quaternary (more than 1.6 million years ago) deformation disrupting an otherwise homoclinal (i.e. bedding layers tilted in one direction as a singular structural block), northeast-dipping structure across the site.

The Iverson syncline, Rocky Peak anticline, and Devil Canyon anticline are mapped projecting onto the west side of the property. Synclines are folds forming a trough-shaped bend in bedding planes and anticlines are those forming crest-shaped bends. These folds were either removed or confirmed as folds by field mapping and/or using the backhoe to scrape shallow bedrock exposures. The approximate locations of these fold axes are shown on Plates 4 & 5. Two lineaments were reviewed that appeared to coincide with an onsite projection of the Northridge Hills fault (NHF). One coincides with mapping by Evans (1978) of a "shear zone" and was observed in the field to be along bedding displacement. A shear zone is a zone along which earth units have been displaced. This feature was observed in the field and appeared to be minor displacement along bedding. These along-bedding shears are typical of folded sediments consisting of interbedded layers of materials having unique shear strengths and represents differential slip during folding events. As described previously, folding associated with the Chatsworth Formation is believed to be pre-Quaternary.

Aerial photographs were reviewed to assess the presence of linear features (photolineaments) onsite or immediately adjacent to and projecting toward the site that may represent a potential for onsite faulting. Fold axes such as the Iverson syncline were not observable but were confirmed

by field mapping of bedrock structure. Three sets of lineaments were mapped including (from south to north):

- Northwest-trending, central lineament “A” (see Plate 10) – This lineament may align with onsite projection of Northridge Hills fault (Jennings, 1994). It is discontinuous, poorly expressed by linear vegetation contrasts, and some degree of alignment of breaks in ridgelines and slopes.
- Northwest-trending, northern lineament “B” (see Plate 10) – Aligns with Evans’ (1975) shear zone and is poorly expressed as described for the above lineament, but considerably more continuous.
- West/Southwest-trending northern lineament “C” (see Plate 10) – Three lineaments in and offsite of the northeast corner of the site are moderately well expressed by vegetation contrasts and topography. These lineaments align with the Devonshire fault mapped by Yerkes (1995).

Although none of these photolineaments align with faults with known Holocene rupture and/or lie within an Alquist-Priolo Earthquake Fault Zone, two exploratory trenches were excavated and logged and one backhoe shallow pit was excavated across selected segments of the photolineaments. Logs of these two trenches are provided in Appendix E and are located on Plates 13 and 14. Subsurface exposures confirmed surface mapping of outcrops concluding that along-bedding shearing occurs preferentially within the weaker (finer-grained), siltstone beds of the Chatsworth Formation. Although Pleistocene stratigraphy was not present in these trenches to preclude Holocene displacement, surface mapping during this study and previous geologists findings conclude that these faults do not cut Plio-Pleistocene Saugus Formation deposits, where present.

3.2 SEISMICITY

Faults mapped in this portion of Southern California that may generate earthquakes that could significantly influence the site are shown on Plate 3 (Jennings, 1994) and are summarized in Table 1 (Significant Faults) relative to their site distance, maximum moment magnitude, and seismic source type.

**Table 1
Significant Faults**

Fault Name	Approx. Site Distance Km (mi)	Maximum Moment Magnitude	Seismic Source Type (1)
Santa Susana	2.4 (1.5)	6.6	B
Simi	6.0 (3.7)	6.7	B
San Fernando (Mission Wells)	9.6 (6.0)	6.7	B
Verdugo	14.4 (9.0)	6.7	B
San Gabriel	15.4 (9.6)	7.0	A
San Andreas (Mojave)	46 (29)	7.9	A

(1) A – M (magnitude) ≥ 7.0 & SR (slip rate) ≥ 5.0 mm/yr, C – M < 6.5 & SR ≤ 2.0 mm/yr, B – all other faults.

Future seismicity at the site can be estimated using both deterministic and probabilistic methods. Deterministic evaluations assume a defined event occurs and probabilistic methods consider the probability of that event. In recent years, probabilistic methods have found wider recognition among seismologists. Ground shaking due to earthquakes is expressed in terms of ground acceleration values for a peak (initial) condition. The peak horizontal ground acceleration (PGA) for the site was first evaluated deterministically assuming a 6.6 moment magnitude event (similar to that of the 1994 Northridge event) along the Santa Susana fault at a distance of 2.4 km (1.5 miles) from the site. Based upon the mean rock value using Abrahamson and Silva's 1997 attenuation model, an acceleration of 0.87g is estimated for rock, 0.59g for soil, and an average value of 0.73g was computed by averaging for the soft rock conditions at the site. A probabilistic acceleration of $> 0.70g$ was estimated from the Probabilistic Seismic Hazard Map (Peterson et al, 1999) for a 10% probability of exceedance in 50 years (Design Basis Earthquake; DBE) and soft rock sites (Plate 11). Based on a comparison of these two unique values, a value of 0.73g appears to accommodate either basis.

3.3 LIQUEFACTION

Liquefaction is the loss of soil strength due to sudden shock (as caused by earthquake shaking) that causes the soil to become a fluid mass. In general, for the effects of liquefaction to be manifested at the ground surface, groundwater levels must be within 50 feet of the surface and the soils within the saturated zone must also be susceptible to liquefaction. Finer grained soils, including silts and clays are less susceptible to liquefaction than coarser grained soils. Loose, silty to clean fine sands are generally the soils most susceptible to liquefaction.

The site is located within a liquefaction hazard zone, as shown on the Seismic Hazard Zones Map (Plate 12). Liquefaction at the site was evaluated in accordance with screening methods described within SP117 (CDMG, 1997). Essentially all of the site is underlain by shallow, dense bedrock. The only surficial deposits that could not be ruled out by a screening level analysis and thus concluded to be "clearly non-liquefiable" are shallow soils located in the drainages across the site and the deeper alluvium along the bottom of the canyons and tributaries. Shallow soils across the site will be removed during site earthwork and deeper alluviated tributaries located outside of the proposed development areas. The liquefaction potential at this site is therefore considered to be very low and liquefaction investigation or analysis is not considered to be necessary.

Seismically induced settlement of alluvial soil or engineered fill may occur, especially where deep fills are planned. Differential settlement of deep canyon fills where large differences in fill depths across building pads is of concern. In planned building areas and access road alignments, removal of alluvial soils to bedrock and remedial grading to reduce differences in fill thickness under structures may reduce the settlement potentials.

3.4 SLOPE STABILITY

The proposed development site is located within a Seismically-Induced Landslide hazard zone, as shown on the Seismic Hazard Map (Plate 12). Slope stability at this hillside site requires consideration of both natural and proposed slopes. The performance of onsite earth units is clearly defined by the presence of several landslides and surficial slope failures and areas of instability. As shown on Plates 13 and 14, three primary types of failures were mapped, including:

- Translational (along bedding) bedrock failures within dip-slopes of the Chico sandstone;
- Rotational bedrock failures within anti-dip slopes of the Chico sandstone and massive Saugus Formation, and;
- Surficial instability including shallow toppling rock slope failures, rock creep in zones of moderately to highly weathered Chico Sandstone, and soil creep and shallow slumps within soils and colluvium formed over both Chico and Saugus Formation materials.

Many of these slopes are suspected to have failed during recent high intensity shaking due to the 1994 Northridge earthquake.

Our analysis of existing natural slopes and proposed cut slopes considered all three of these styles of failure. All slopes, either natural or man-made will be subject to strong ground shaking and were therefore analyzed taking into consideration potential seismic loading. The following sections describe our methods and results of slope stability analyses.

3.4.1 Existing Landslide Reactivation

Three landslides were mapped within the area of influence of the proposed development footprint. Each is mapped and numbered for correspondence with this text and related tables on Plates 13 and 14. Landslide Q1s-1 occurred along a portion of Devil's Canyon north of Lots 52-55 and is depicted in cross-section C-C'. This landslide is a translational failure in Chatsworth Formation (sandstone) bedrock and is considered capable of reactivation influencing upslope lots.

Landslide Q1s-2 is located north of Lots 26-34 and is depicted by Cross-Section G-G'. This slide is also interpreted to be a translational Chatsworth Formation failure and is similarly considered capable of reactivation and influence to the above lots.

Landslide Q1s-3 is located north of Lots 180-181 and is depicted by Cross-Sections Q-Q' and P-P'. This slide occurred within a tributary canyon adjacent to these two lots and, if reactivated, would contribute quantities of debris into this drainage. Young tension cracks behind the headscarp suggest that this slide is recent and may have occurred during the 1994 Northridge earthquake.

3.4.2 Natural and Proposed Slopes

Natural and proposed cut slopes were analyzed by first identifying susceptible slopes based on location relative to the proposed development, steepness, and height, in accordance with County design guidelines. Susceptible slopes are numbered on Plates 13 and 14 and a cross-section is constructed through each location. A summary of these slopes is provided in Appendix D.

3.4.2.1 Strength Parameters

Existing natural slopes, proposed cut slopes, and proposed fill slopes required global slope stability analyses. Strength parameters for these analyses were selected on the basis of observed subsurface characteristics, rock slope traverses to develop Rock Mass Ratings (RMR), laboratory testing, and experience within similar earth units. Strength parameters were developed for along-bedding and across-bedding within the Chatsworth Formation, the Saugus Formation (assumed isotropic), and homogenous engineered fill. Across-bedding strengths within the Chatsworth Formation were developed by performing rock slope traverses in the areas of cross-section L-L' and G-G'. Data was obtained from traverses to compute RMR including observed strength, Rock Quality Designation (RQD), spacing, condition, and orientation of discontinuities, and groundwater conditions (Bieniawski, 1989). RMR values obtained for these areas were then compared to correlation tables (ISRM, 1981; Hoek and Bray, 1981) unconfined compressive strength values and then converted to corresponding phi (ϕ) and cohesion (c) values of 28° and 4,000 psf, respectively. A more detailed description of field methods and obtained data is provided in Appendix A. Along-bedding strength values for the Chatsworth Formation were developed by back calculation of the Q1s-1 failure and a remolded-residual reshear test from samples obtained from Boring KA-1.

3.4.2.2 Analytical Methods

Slope stability analyses were generally performed using two methods. Initially, rock slopes were analyzed using Xstabl® based on strength values described above. This method of analysis was used to analyze slope 7 (Section L-L'). For comparison purposes and to assess the reliability of rotational and translational analyses for other slope areas, this area was also analyzed using Janbu (rotational) and Bishops Modified (translational) failure analytical models. A static FOS of 1.82 was computed using Bishops method as compared to 1.9 using Xstable. Both methods were therefore considered applicable and were used to develop FOS values for each natural slope area or proposed cut slope. The results of our analyses are provided in Appendix C along with a table summarizing style of failure analyzed, slope type and materials, Factor of Safety (FOS), and findings. Fill slopes were also analyzed on an individual basis and were found to be stable as designed at a 2:1 (H:V) slope gradient. All slopes requiring stabilization are discussed further in Conclusions and Recommendations later in this report and stabilization measures are depicted on the Site Plan and Geologic Maps (Plates 13 and 14) and corresponding Cross-Sections (Plates 15 and 16).

3.4.3 Surficial Failures and Debris Flows

Slope analyses described above were performed to evaluate global stability and do not address near surface “surficial” stability performance of natural, cut slopes, and/or fill slopes. All slopes will be exposed to weathering, resulting in decomposition of surficial earth materials, thus reducing shear strength properties. In addition, these slopes become increasingly susceptible to rodent burrowing. As these slopes deteriorate, they can be expected to become susceptible to surficial instability such as soil slumps, erosion, rock creep, soil creep, and debris flows. Therefore, development areas immediately adjacent to ascending or descending natural or proposed cut slopes should address future sloughing of debris.

The deeply incised drainage channel of Devil Canyon contains many areas of surficial failures of soil over bedrock. In addition, planned fill slopes and cut slopes within the Saugus Formation may also be prone to surficial failures if the slopes are not properly designed, constructed, and maintained.

Debris flows hazards commonly exist near steep slopes where slopewash or colluvium drape the hillsides and where drainages are well-defined and sediments have accumulated. In the northern portion of the planned development, there are several moderately to well-defined drainage courses that will be affected by the planned grading and creation of south facing cut slopes. Where the cut faces intersect these drainages, flooding and debris flow potentials are considered moderate to high. A review of these specific hazards and development of specific mitigation measures should be implemented at the 40-scale grading plan design stage.

Erosion of existing hillsides, especially adjacent to the well-defined drainage courses is apparent within alluvial/colluvial materials. Bedrock areas are generally not prone to significant erosion.

3.5 TSUNAMI, SEICHE, AND RESERVOIR FAILURE

Due to the site’s elevated inland location, hazards from tsunamis are considered nil. Currently there are no water storage reservoirs located upgradient from the site. As such, hazards for reservoir failures or seiches are considered nil at this time. In the event that future storage facilities are located upgradient of the site, consideration of potential flood hazards should be included in the project design.

3.6 COMPRESSIBLE SOILS

The majority of the site is underlain by dense sandstone of the Chatsworth Formation and dense, weakly- to moderately-cemented sands of the Saugus Formation. Neither of these units are expected to be compressible. However, residual soil profiles, colluvium, alluvium, and slope wash generated from either of these units will likely be compressible. Landslide and surficial slope failures are also expected to be compressible. The extent of these earth units relative to the tentative map design is restricted to soil, colluvium, and localized surficial slope failures as mapped within the development area (Plates 13 and 14). Alluvium and slope wash are present outside of the proposed development areas.

3.7 EXPANSIVE SOILS

Expansive soils are restricted to those clayey units onsite that may undergo shrinkage/expansion when subjected to significant changes in moisture content. Potentially clay-rich materials are known to occur as strata within the Saugus Formation but were not observed on the site. Clay-rich zones within the Chatsworth Formation are also known to exist and were observed during our field exploration and are relatively localized and difficult to predict their location and extent. These zones are also expected to be only moderately expansive, if present. Soil profiles and colluvium may also be moderately expansive. Fill generated from any or all of the above earth units are expected to range from low to moderate expansion potential. Expansion tests were not performed on samples collected during our field exploration for this tentative tract design-level study.

3.8 SOIL CORROSIVITY AND CONCRETE REACTION

Representative samples were collected from the Saugus and Chatsworth Formations at three locations distributed across the development area. These samples were analyzed for sulfate content, chlorides, pH, and resistivity. The results of these analysis are presented in Appendix B.

4 CONCLUSIONS AND RECOMMENDATIONS

This report summarizes our investigation of the site intended for a tentative tract design-level study. Based upon Los Angeles County Department of Public Works guidelines, the level of investigative effort needs to emphasize those issues which may represent a fatal flaw resulting in unbuildable lots and/or infrastructure, as tentatively designed. Based upon the results obtained during this research, geologic mapping, and preliminary geologic exploration evaluation of the site, it is our opinion that the proposed project is feasible from a geologic and geotechnical perspective, provided the recommendations presented in this report are properly incorporated into project planning, design, and construction. It is Kleinfelder's professional opinion that the proposed development will not be subject to hazards relating to landslides, settlement or slippage provided the recommendations of this report and future design-level studies (i.e. grading plan review stage) are incorporated into project design and construction. It is also our professional opinion that the proposed improvements will not adversely affect the geologic stability of the site or adjacent properties provided the recommendations of this report are incorporated into project design and construction. Statements of professional opinion do not constitute a warranty or guarantee. The following sections of this report provide a summary of potential geologic and/or geotechnical conditions, and potential impacts on the project.

Two bridges are proposed as part of the infrastructure for this subdivision. Preliminary geotechnical information for the design of abutments and piers for those proposed bridges is provided in Appendix G, herein.

The following sections of this report summarize our conclusions regarding potentially adverse subsurface conditions and, where concluded to be adverse, general recommendations for mitigation.

4.1 GROUND RUPTURE POTENTIAL

The potential for ground rupture at the site is believed to be restricted to minor sympathetic adjustment of older faults. Although the site is situated in the general vicinity of the 1994 Northridge Earthquake, preliminary studies at the site indicate there are no Holocene (i.e active) faults onsite. However, inactive (i.e. pre-Holocene) faults are present onsite that represent old zones of weakness. In these locations, the influence of any minor displacement, should it occur,

may be mitigated by constructing a uniform, engineered fill cap in conjunction with stiffened foundation systems capable of tolerating such subsurface conditions. The depth of removal and recompaction associated with construction of these fill caps should be on the order of 5 to 10 feet to provide a homogenous buffer to the overlying foundations. The precise locations of these fill caps, including thicknesses, will be developed as part of a detailed geotechnical report in conjunction with final project grading plans.

4.2 SEISMIC CONSIDERATIONS

Mean peak ground accelerations from the anticipated maximum earthquake are expected to be approximately 0.73g based upon probabilistic and deterministic analysis described earlier. Seismic design of structures should be based on the UBC (Uniform Building Code) 1997 seismic design methods incorporating the PGA values computed herein in Section 3.2. The Santa Susana fault is the source fault (Source Type B) and is between 2 and 5 km from the site. 1997 UBC seismic design criteria are provided in the following table.

Table 2
Summary of Seismic Design Parameters

Seismic Zone	4
Seismic Source Type (Santa Susana Fault)	B
Distance from Seismic Source	2 km
Soil Profile Classification (1997 UBC Table 16-J)	S _c
Seismic Zone Factor – Z (1997 UBC Table 16-I)	0.40
Seismic Coefficient - C _a (1997 UBC Table 16-Q)	0.40N _a
Seismic Coefficient - C _v (1997 UBC Table 16-R)	0.56N _v
Near Source Factor - N _a (1997 UBC Table 16-S)	1.3
Near Source Factor - N _v (1997 UBC Table 16-T)	1.6
Horizontal Acceleration (DBE)*	0.73g

*10% probability of being exceeded in 50 years

4.3 GROUNDWATER AND SUBDRAINAGE

Groundwater conditions at the site are primarily restricted to tributaries and drainages where seepage was observed in Browns and Devils Canyons. Development is not proposed in these areas. Regional groundwater beneath the site is on the order of 360 feet below site grades. However, earthwork may create fill-over-cut permeability contacts along which seepage may occur such as backyards having fill-over-cut slopes. Once grading plans have been developed for the project, these areas should be identified and subdrain systems with adequate outlet

systems should be designed. It should be understood that precise location of these drainage systems cannot be designed even with grading plans and will need to be verified by the project geologist and/or geotechnical engineer during grading.

4.4 LIQUEFACTION

Portions of the site are located in a liquefaction hazard zone according to the Seismic Hazard Zones Map by CDMG. In accordance with the CDMG SP 117 Guidelines, a screening level liquefaction evaluation was performed concluding that the potentially liquefiable soils onsite are present only in the alluviated drainages outside of the development areas. The only potentially liquefiable soil known to be present within the proposed development areas are the near-surface residual and colluvial soil which are expected to be removed by excavation in cut areas or removed in advance of fill placement. Therefore, the liquefaction hazard onsite is believed to be very low and no further liquefaction evaluation is considered necessary. The canyon bottom alluvium located outside the area proposed for development may be subject to potential liquefaction. This issue will be addressed for each bridge in the bridge design reports.

4.5 SLOPE STABILIZATION

Slopes that may influence the proposed development include existing natural slopes, surficial failures, and landslides as well as proposed cut slopes and fill slopes. The potential for debris flow generation onsite is also addressed in this section. Stability analysis of each of these conditions was performed by first evaluating the presence and style of slope instability at the site in its undeveloped condition. These observations were then used as a basis for determining the method of analysis most appropriate for onsite conditions. A summary of our analytical methods, input parameters selection, and findings (Appendix C) is provided in a previous section 3.4. In general, global slope stability was found to be favorable with the exception of the north-facing canyon wall along Devils Canyon, due to adversely-oriented bedding planes. All proposed cut slopes and fill slopes were found to be stable against global instability. Surficial instability is present along steeper portions of natural slopes and as proposed cut slopes and fill slopes deteriorate with time. Debris flows and debris generation are anticipated within tributary drainages adjacent to areas of proposed development. The following sections describe areas concluded to be unstable thus requiring stabilization.

Table C-1 in Appendix C summarizes all the analysis performed and the resulting factors of safety for each analysis. The analysis shows both existing and proposed factors of safety for the

slopes that did not achieve a minimum factor of safety of 1.5. For slopes that achieved a factor of safety of less than 1.5 for static stability, we considered and evaluated several remediation alternatives. A description of all the remediation measures considered are presented below.

4.5.1 Existing Landslides

Three landslides have been mapped that are within the area of influence of the proposed development. Each is shown on Plates 13 and 14 and are discussed in section 3.4.1. Our analyses were used as a basis for the following recommendations:

Landslide Qls-1: A setback has been established from the landslide and potentially unstable upslope conditions. This setback area has been defined on the basis of a projection of the landslide rupture surface along bedding and is shown on Cross-Section C-C' and on Plate 13 for use in establishing an appropriate Restricted Use Area. Analyses were performed to evaluate the stability of underlying, undisturbed bedding planes, concluding a minimum FOS of 1.4 for that area accommodated by this setback. This setback line is approximately 100 feet south of the daylight cut limits. A factor of safety of 1.5 was calculated for that area outside of the 100 foot setback line as shown on Plate 13.

Landslide Qls-2: Bedding planes beneath this landslide were found to yield inadequate FOS's and thus will require stabilization. This shear key is 50 feet wide by 50 feet deep and is shown on Cross-Section G-G' and Plate 13. A reinforced Earth slope is proposed towards the top of the slope for the area by Section G-G'. The reinforced earth slope is required to be constructed to increase the factor of safety of the existing slope to 1.5 from 1.4. In general the reinforced earth slope will consist of engineered fill and geogrids installed at 8 levels to provide the necessary reinforcement to stabilize the slope. Soils used for reinforced fills should be placed in accordance with the recommendations as described below.

Before placing Miragrid geogrids, the surface should be cleared of all debris and the foundation base proofrolled. The grids should be rolled out, cut to length, thus eliminating field connections; and laid at the proper elevation, location and orientation. Since geogrids vary in strength with roll direction, Miragrid should be laid in the direction of main reinforcement.

After rolling out, the material should be tensioned by hand until it is taut, free of wrinkles, and lying flat. Adjacent geogrid rolls may be butted together side-by-side without overlap. Splices should be avoided.

Certain fill placement procedures may require the reinforcement to be held in place by stakes, sandbags, or fills, as directed by an engineer. A razor blade, sharp knife or scissors may be used to cut the material. Fill placement should follow the standard practice, or as defined in the project specifications or directed by the engineer. Care should be taken to prevent wrinkles and/or slippage of reinforcement during fill placement and spreading.

The reinforced earth slope will be 50 feet wide at the base and 50 feet wide at the top and about 50 feet high. There should be 16 equally spaced layers of Mirafi Miragrid 5XT (or equal) product placed in accordance with the manufacturer recommendations. The primary reinforcements will be about 50 feet long measured from the slope face at their corresponding elevations. The finished slope face will be approximately 1:0.8 (h:v), although a less steep slope is acceptable. The back cut will also be 2.0:1 (h:v). The FS against slope stability for the reinforced earth slope was 2.6. The computer program Miraslope by Mirafi was used in evaluation the stability of the reinforced slope. All slope facing should be wrapped with the geogrids and the geogrid should be extended a minimum of 10 feet into the slope. Fill should be placed at a minimum of 92 percent relative compaction at a moisture condition above but within 3 percent of the optimum per ASTM test method D-1557. The required reinforcement of the fill slope can be achieved utilizing geogrid consisting of Mirafi EXT or equivalent grid placed within the fill at 3-foot vertical intervals through the entire height of the slope. The first layer should be at 2 feet above the bottom of the keyway and the uppermost layer should be at 4 feet below finished grade in the rear yards of the homes. The individual layers of geogrid shall extend, laterally from within 12 inches of the face of the finished slope to the back of the excavation. Where necessary, to cover width of the filled area, overlap of the geogrid shall be a minimum of 18 inches. Special care shall be taken by the contractor to avoid damage to the geogrid by earthwork equipment during fill placement and compaction. We recommend a minimum of 9 to 12 inches (loose thickness) of fill material be placed over the geogrid prior to working with compaction equipment.

Landslide Qls-3: This landslide is unstable and will likely reactivate. If this slide reactivated, it would contribute large quantities of debris into the existing designed debris basin. At the grading plan review stage, the volume of this basin should be evaluated and resized to accommodate this debris or the slide should be completely removed.

4.5.2 Natural Slopes and Surficial Failures

The global stability of natural slopes was evaluated by individual analysis of slopes by underlying earth unit, orientation, height and steepness as outlined in Appendix D. Our analyses of these slopes concluded that only Natural Slope Nos. 4 and 5 are unstable. Setback recommendations are provided for Natural Slope 4 on Plate 13 and on Cross-Section C-C' and are explained in greater detail in section 4.5.1, above. A shear key is proposed for Slope 5, as also previously discussed.

All lots, infrastructure, and other site improvement proposed at the top or toe of existing natural slopes may be influenced by potential surficial instability of these natural slopes. Once 40-scale grading plans become available, these areas should be identified and adequate setbacks, if required, should be established on the basis of slope gradient and condition at that time. These setbacks are not considered to present a substantial geotechnical impact to the feasibility of proposed lots at this time. If these setbacks cannot be established, routine surficial slope stabilization methods can be incorporated such as retaining walls, catchment areas or walls, or deepened foundations that penetrate the depth of potential surficial failure. Specific areas for such mitigation will be identified in the final geotechnical report in conjunction with the final 40-scale grading plan.

4.5.3 Cut Slopes and Fill Slopes

There are 6 cut slopes higher than 50 feet and 4 fill major slopes planned for this project. All proposed cut slopes and fill slopes are designed at a slope gradient of 2:1 (H:V). The 6 cut slopes and 4 fill slopes were analyzed for global stability and were found to be stable as designed.

These slopes will be constructed using typical slope drainage systems in accordance with UBC (1997) including mid-slope drainage swales and brow ditches and are subject to typical homeowners maintenance requirements.

4.5.4 Debris Flow Generation

Several areas of potential debris flow generation have been identified along the norther property boundary. These areas are represented by proposed areas of development adjacent to tributary

drainages. Debris basins have been designed at each of these locations and are shown on the Vesting Tentative Tract Map used as a base map for Plates 13 and 14.

4.6 TEMPORARY STABILITY OF BACKCUTS

Temporary cuts will be necessary when excavating shear keys such as that proposed at natural Slope 5 (and landslide Qls-2). Since stabilization is being performed in areas found to be unstable in their current configuration, steeper backcuts are unstable by definition. The stability of proposed backcuts should be analyzed during the grading plan review stage when greater design detail is available. Backcuts should not be excavated especially where worker safety or stability of adjacent structures may be jeopardized until stability analyses can be performed and safety measures developed.

4.7 TSUNAMI, SEICHE, AND RESERVOIR FAILURE

Due to the inland location of the site, hazards from tsunamis are considered nonexistent. As no water storage reservoirs are currently located near the site, hazards from seismically induced seiches or reservoir failure at the site are considered low at this time.

4.8 REMOVAL OF COMPRESSIBLE SOILS

Colluvium and topsoil will generally be removed as a normal part of the mass excavation process. Where fills are planned, normal to heavy benching operations will frequently result in complete removal on slopes steeper than 5:1. On slopes flatter than 5:1 and in drainage swales, separate cleanout operations may be necessary. For planning purposes, we estimate a removal thickness of less than 5 feet in swales prior to typical benching.

4.9 EXPANSIVE SOILS

Expansion testing was not performed as part of this scope of work. Moderately expansive siltstone and claystone may occur as beds within sandstone and conglomerate layers of the Chatsworth Formation; the most common earth unit at the site. Cut pad areas exposing these potentially moderately expansive interbeds may be susceptible to differential expansion during wetting and drying cycles. Differential expansion could influence the design of pavements, building foundations, and hardscape and/or will require removal and recompaction with non-expansive soils. Final lot and foundation design should be based on lot-specific data collected

during future detailed design stages and upon exposure of final pad grade materials during construction.

4.10 SOIL CORROSION AND CONCRETE REACTION POTENTIAL

Six samples of the subsurface soils obtained from our exploratory borings were tested for preliminary potential corrosion to concrete and reinforcing steel. The material was tested for pH, resistivity, soluble sulfates and soluble chlorides. The results of the preliminary corrosion tests are presented in Appendix B.

Based on the preliminary corrosion screening tests, the corrosion values from the soils tested are normally considered to have be representative of soils with a low corrosivity towards concrete and a high to severe corrosivity toward buried metals. Kleinfelder does not practice corrosion engineering. We recommend that a corrosion engineer be retained to evaluate the corrosion potential of the site to proposed improvements, to recommend further testing as required, and to provide specific corrosion mitigation methods appropriate for the project. We have provided the above corrosion tests as requested by the client. These tests are only a preliminary indicator of soil corrosivity for the samples tested. Other soils found on site may be more, less, or of a similar corrosive nature.

4.11 SHRINKAGE/BULKING AND SUBSIDENCE

Materials excavated for re-use as fills may shrink or bulk depending on their in-situ density and compaction characteristics. The degree of shrinkage or bulking will vary with depth and earth unit. Earth units mapped onsite include Saugus Formation sandstone and conglomerate, Chatsworth Formation sandstone, and lower density, surficial deposits including topsoil and colluvium. Shrinkage and bulking factors are very difficult to estimate because of the natural variability of earth materials and other unknowns. The recommended shrinkage and bulking values presented are estimates only and should be used accordingly. Since the majority of the planned development at the site will occur within the Chatsworth Formation, the overall subsidence resulting from surface compaction and the placement of fill is expected to be less than 0.1 foot. Although subsurface exploration, sampling, and laboratory analyses will need to be performed to provide shrink/bulk estimates to be used in conjunction with design civil and contractor information for similar projects in similar earth units, we estimate these values for preliminary planning purposes as follows:

- **Saugus Formation (QTs)** occurs along the northern project boundary and is moderately dense. Several cut slopes may occur in this area and, although this earth unit probably does not represent the primary source of fill materials, it will be a factor in computing the earthwork balance. Excavations to approximately 20 feet below existing grade should be expected to experience very little shrinkage/bulking. Deeper cuts may bulk slightly between 0 and 5%.
- **Chatsworth Formation (Kcs)** represents the most widely distributed earth unit onsite and thus will become the primary source of fill materials. This unit is older and more dense than the Saugus Formation and can be expected to bulk. Bulking will vary with depth substantially as described by seismic refraction studies. For planning purposes, this unit should be estimated to bulk approximately 5 to 8 percent in the upper 25 feet and between 8 to 10 percent deeper than 25 feet.
- **Shallow topsoil and colluvium** represents a small portion of the excavation for the project but will shrink substantially due to its low density nature. For planning purposes, we estimate that the shrinkage associated with the on-site colluvium will be on the order of 10 to 15 percent.

4.12 SUITABILITY OF ONSITE SOILS AS FILL MATERIALS

The on-site soils encountered during our site exploration, excluding debris and/or other deleterious materials, are considered suitable for use as engineered fill. When adequately compacted at an appropriate moisture content, these materials can be expected to possess suitable bearing and settlement characteristics for the proposed construction.

Based on the sandy nature of the potential fill materials to be placed in deep canyon areas, we expect that most of the settlement will occur during construction. We estimate that about 1 to 2 inches of settlement may occur as post-construction settlement resulting from placement of 80 feet of engineered fill. We recommend that a fill settlement monitoring plan be developed and implemented for all fills deeper than 50 feet.

4.13 RIPPABILITY OF EARTH UNITS

Seismic refraction studies were performed by others during previous studies concluded that the Chatsworth sandstone units (the hardest of onsite earth units) may be difficult to excavate below

a depth of about 25 feet below existing ground surfaces. The locations of these profiles are shown on Plates 13 and 14. Ground velocities obtained from the refraction survey were correlated with the findings of the subsurface exploration program. Generally, the surficial units were concluded to be excavatable with typical suitably sized hillside earthwork equipment in good operating condition.

Seismic or ground velocity and rock type are not the only indicators of rippability. Penetration of the ripper tooth into the material regardless of seismic velocity is often the key to successful ripping. The uniformity or homogeneity of the material, degree and type of cementation, alteration, or weathering, and rock type also factor into the ability of a rock material to be effectively ripped. Structures within the rock, such as faulting, shear zones, foliation, fractures, jointing, and the direction of the ripping pattern with respect to the orientation of these structures also affect the ability of the rock material to be ripped without pre-blasting. Additional seismic refraction analyses in conjunction with rock coring to assess fracture spacing and character can be conducted as part of the final geotechnical report in conjunction with the final project 40-scale grading plan.

Excavations in rock areas will produce oversized rock (i.e. rock greater than six inches in maximum dimension). Oversized rock greater than six inches in size but less than three feet may be placed in the deeper fill areas where settlement considerations can be addressed and where deep utilities are not proposed. The larger rock will require special handling to reduce its size or place as windrows in a rock disposal fill.

4.14 GENERAL EARTHWORK AND GRADING RECOMMENDATIONS

General grading and earthwork guidelines are provided in Appendix F, herein. These guidelines are general in nature and pertain to "typical" earthwork in hillside environments. Preliminary, site specific recommendations are contained in the report text and, where redundant with the grading and earthwork guidelines, should supercede those recommendations

4.15 RETAINING WALLS

Retaining walls will be required in localized areas throughout the project site to facilitate the proposed grade separations depicted on the grading plans. Our preliminary design recommendations are presented in the following sections for the various wall locations and

planned wall types. Final geotechnical design recommendations will be provided at the 40-scale plan stage.

4.15.1 Proposed Walls

Wall 1 – Wall Below Lots 435-438 (Section M-M'). The preliminary design of the wall system below lots 435 through 438 consists of a set of 5 individual walls tiered down the existing slope to provide the required grade change of 90 feet in a horizontal distance of approximately 65 feet. The individual walls will retain up to approximately 10 feet of engineered fill sloped at approximately 2:1 (H:V). Deepened footings will be required to maintain adequate distance between the edge of footing and the slope face and the walls may need to be designed for surcharge pressures of the upslope adjacent wall. Depending on site constraints and final design configuration, drilled piers with permanent lagging walls may be required or may be the most feasible construction method. With this option, tie back anchors may be required for the upper walls where up to 40 feet of fill is to be placed.

4.15.2 Structural Reinforcement

Structural reinforcement of the slopes by use of soldier pile walls and tie-back or rock anchors is also a remediation alternative that can be used to increase slope factor of safety to greater than 1.5. Section M-M may require a combination of a mechanically stabilized earth wall and drill pier and grade beams. The drilled piers should be installed close to the daylight line and will most likely be on the order of 4-foot diameter at approximately 8-feet on center. The piers will need to be about 100 feet deep and may also need to be tied back. Design of a structural reinforcement system is not within the scope of this proposal; however, we can furnish these design alternatives and associated costs upon request.

Wall 2 – Wall Below Lots 85 to 90 (Section H-H'). A 10-foot high retaining wall is proposed at the toe of the slope that descends from lots 85 to 90. The retaining wall will support an approximate 2:1 (H:V) engineered fill slope. Standard masonry block or reinforced concrete construction may be used for the wall. Wall foundations may consist of shallow spread foundations once any unsuitable alluvial deposits are overexcavated and replaced as engineered fill or drilled piers extending into competent sandstone materials. The alluvial materials are mapped to be on the order of 10 feet in thickness.

Wall 3 – Wall Back of Lots 41 through 44 (Sections E-E and F-F’). A 6- foot high retaining wall is shown on the grading plan at the back of lots 41 through 44. Typical masonry block or reinforced concrete construction is anticipated with shallow spread-type foundations. The wall is planned at the top of a natural slope, and will probably require founding in competent bedrock.

Wall 4 – Midslope Wall Below Lots 104 and 105 (Section I-I’). A minor retaining wall is preliminarily planned to be constructed at about elevation 1,200 feet on the proposed engineered fill slope below lots 104 and 105. The wall is planned to be located between B Street and the proposed horse trail. The wall is anticipated to be approximately 4 to 6 feet in height, of masonry or reinforced concrete construction, and supported on shallow spread foundations supported in engineered fill.

Wall 5 – Within Lots 334 through 337 (Section U-U’). A high retaining wall is planned within lots 334 through 337 to maintain required line-of-site for the curve in B Street. The wall will be on the order of 20 feet in height. We anticipate the wall will be of reinforced concrete construction and will retain level to 2:1 sloping ground. We anticipate the wall may be supported on shallow spread foundations. Walls taller than 15 to 20 feet may need to be tied back or braced depending on the actual earth pressures used in design. A MSE (mechanically-stabilized earth) retaining wall could be considered at this location. Construction would receive some overexcavation of bedrock materials to allow the placement of the soil reinforcement (geogrids) that typically extend a distance behind the wall of 0.7 to 0.85 times the height of the wall.

Wall 6 – Above Lots 332 and 333 (Section N-N’). A midslope, approximately 2- to 6-foot high, retaining wall is planned to be constructed on the proposed cut slope northeast of lots 332 and 333. We anticipate the wall will be of masonry block or reinforced concrete construction and will be supported on shallow spread foundations in the underlying bedrock.

Wall 7 – Retaining Wall Below Rock Pedestal (Section T-T’). A retaining wall is planned approximately 20 feet east of the rock pedestal and 10 to 30 feet east of B Street near the southern tip of the site. Due to the out-of-slope bedding conditions that will be exposed by the construction of the wall, the wall will need to be designed to resist the potential downslope movements of the rock mass above the toe of the retaining wall, which will be highly influenced by the large rock pedestal located west of the wall. We anticipate that the required design pressures to resist slope movement with a factor of safety of 1.5 will exceed standard lateral earth pressures. Permanent tie-back anchors may be required for design of the wall.

As an alternative, the use of soil nails or drilled piers to anchor or stabilize the rock mass could be evaluated. This alternative would include installation of drilled piers or soil nails to extend through the lowest plane out-of-slope bedding material that could potentially fail with the proposed cut. The soil nails and/or piers would act as anchors to resist potential downslope movement of the materials and rock pedestal upslope from the soil nails or piers.

4.15.3 Preliminary Design Recommendations for Walls Below Grade

Lateral Earth Pressures

The following preliminary recommendations are presented for preliminary design and feasibility analyses of retaining walls. Active lateral earth pressures from horizontal backfill using the on-site native soils on walls that are free to rotate at least 0.1 percent of the wall height can be taken as equivalent to a fluid weighing 30 pounds per cubic foot (pcf). Walls which are restrained against movement or rotation at the top should be designed for an at-rest equivalent fluid pressure of 50 pcf or a uniform pressure of $24H$ psf, where H is the height of the wall in feet. These values do not include additional lateral surcharge to adjacent foundations or traffic. Lateral load resistance may be derived from passive resistance along the vertical sides of the footings, friction acting at the base of the footing, or a combination of the two. An allowable passive earth pressure of 300 psf per foot of depth may be used for design.

The above preliminary values are applicable if the on-site soils are used for backfill behind the walls. The recommended value does not include compaction- or truck-induced wall pressures. Care must be taken during the compaction operation not to overstress the wall. Heavy construction equipment should be maintained a distance of at least 3 feet away from the walls while the backfill soils are being placed. Hand-operated compaction equipment should be used to compact the backfill soils within a 3-foot-wide zone adjacent to the walls.

The recommended lateral earth pressures assume that drainage will be provided behind the walls, by the on site soils, to reduce the potential build up of hydrostatic pressures. Drilling behind walls may consist of a 2-foot wide zone of Class 2 permeable base behind the wall with a collector pipe at the toe of the wall. Alternatively, a drainage board may be used behind the wall that is attached to a collector pipe that will discharge the collected water. The actual backfill materials should be evaluated by the geotechnical engineer prior to placement behind the

retaining walls. The above recommendations will need to be updated based on actual field conditions and the final project design.

Shallow Foundations

Retaining walls that are supported on shallow spread footings bearing on engineered fill and/or competent bedrock materials. Foundations should have a minimum width of 24 inches and should be placed at a minimum depth of 18 inches below the lowest adjacent grade or adjacent finish floor elevation, whichever is lower.

Preliminary geotechnical recommendations for design of foundations on engineered fill are presented below. Confirmation of the bearing value of fill should be conducted prior to final design.

Table 1
Soil Pressure Values

Soil Type	Allowable Bearing	Passive Pressure*	Friction Coefficient**
Engineered Fill	2,000 to 3,000 psf	250 to 300 pcf	0.3 to 0.4
Bedrock	3,000 to 4,000 psf	300 to 350 pcf	0.3 to 0.4

*EFP = Equivalent fluid pressure

**Friction and passive resistance may be combined without reduction.

The recommended bearing value is for total dead plus live loads and may be increased by one-third for wind, seismic or other transient loading conditions.

NOTE: The pressures recommended above were based on the assumption that the on site soils will be compacted to approximately 90% of maximum dry density. The use of select granular fill may lower the recommended driving earth pressure. The resisting pressure provided is an ultimate value. The resisting pressure value may be increased by 1/3 for total loads, including seismic forces.

- Resistance to lateral loading may be provided by friction acting along the foundation base. The coefficient of friction was estimated to be 0.4 for native site soils or for recompacted site soils, and may be used with dead loads. This value includes a reduction factor of one-third. This value may be increased by 1/3 for total loads, including seismic forces.

- The lateral earth pressure to be resisted by retaining walls should be increased to allow for surcharge loads. The surcharge considered should include the loads from any structures or vehicle traffic within a distance approximately equal to the height of the retaining wall.
- Backfill immediately behind any retaining structure should be a free-draining granular material. Comments on the characteristics of import soils will be given by the geotechnical consultant after the material is on the project, either in place, or stockpiled in adequate quantities to complete the project.
- Backfill behind retaining walls should be with soils that have been properly moisture conditioned to approximately optimum moisture content and uniformly compacted to at least 90% of maximum dry density as determined by ASTM D 1557 test procedures using mechanical compaction equipment. To aid in the compaction operation, retaining wall backfill should be placed in maximum six-inch compacted lifts. **Compaction should be verified by testing.**
- Compaction within the area of a 1:1 slope from the bottom of wall excavations should be performed by hand operated compaction equipment. This is intended to reduce potential "locked-in" lateral pressures caused by compaction with heavy grading equipment.
- Weepholes, backdrains, or an equivalent system of backfill drainage should be incorporated into the retaining or subterranean structure wall design (see Appendix F for backdrain details). It is strongly suggested that the drainage fabric (Miradrain™ type material) option be utilized for any project retaining walls.
- The final grade should be such that all water is diverted away from the retaining wall's foundation or backfill.

4.16 PRELIMINARY BRIDGE FOUNDATION RECOMMENDATIONS

Several design concepts have been prepared for the two bridges that cross Devil Canyon. Preliminary recommendations for the bridge foundations are presented in Appendix G of this report. Additional bridge specific investigations will be necessary prior to finalization of the design recommendations.

5 ADDITIONAL SERVICES

This report was based on the assumption that an adequate program of client consultation, construction monitoring, and testing will be performed during the final design and construction phases to check conformance with the recommendations of this report. Maintaining Kleinfelder as the geotechnical engineering consultant from beginning to end of this project will help provide continuity of services. The recommended services include, but are not necessarily limited to, the following:

- Consultation as required during the final design stages of the project.
- Review of pier, foundation, and/or grading plans.
- Observation and testing during site preparation, pier installation operations, placement of engineered fill, and backfill of utility trenches.
- Consultation as required during construction.

6 LIMITATIONS

This report has been prepared for the exclusive use by the Presidio Chatsworth Partners, LLC for specific application to the proposed Tentative Tract 53138, Chatsworth Ridge Estates residential project located in the Chatsworth area of Los Angeles County, California. The findings, conclusions and recommendations presented in this report were prepared in a manner consistent with the standards of care and skill ordinarily exercised by members of its profession practicing under similar conditions in the geographic vicinity and at the time the services will be performed. No warranty or guarantee, expressed or implied, is made. Tentative map or preliminary grading or foundation plans were not available at the time of this evaluation. Our preliminary field exploration for this project was based on the preliminary development concept maps as provided to us by the client.

The client has the responsibility to see that all parties to the project, including the designer, contractor, subcontractors, etc., are made aware of this report in its entirety.

This report may be used only by the client and only for the purposes stated, within a reasonable time from its issuance. Land use, site conditions (both on site and off site) or other factors may change over time, and additional work may be required with the passage of time. Any party other than the client who wishes to use this report for an adjacent or nearby project shall notify Kleinfelder of such intended use. Based on the intended use of this report and the nature of the new project, Kleinfelder may require that additional work be performed and that an updated report be issued. Non-compliance with any of these requirements by the client or anyone else will release Kleinfelder from any liability resulting from the use of this report by any unauthorized party.

The scope of our services did not include any environmental site assessment for the presence or absence of hazardous/toxic materials. Kleinfelder will assume no responsibility or liability whatsoever for any claim, damage, or injury which results from pre-existing hazardous materials being encountered or present on the project site, or from the discovery of such hazardous materials.

APPENDIX A FIELD EXPLORATION

Previous studies at the site performed by other firms, included field explorations by both RMA (1989) and Geosoils (1996). Test pits logged by RMA (1989), and geophysical seismic lines performed by Geosoils (1996) are plotted and included on Plate 12. Copies of logs from the above referenced reports identified on Plate 12 are included in Appendix B.

Kleinfelder's subsurface exploration program for the proposed development during this investigation included the following:

- drilling, sampling, and downhole geologic logging of 13 exploratory large diameter bucket-auger borings,
- drilling, geologic logging and sampling of six exploratory continuous rock cores,
- excavation and logging of 31 exploration backhoe test pits,
- excavation and logging of one fault trench, and,
- geologic mapping of the site.

DRILLING/CORING EXPLORATION

Prior to the onset of subsurface drilling or coring activities, RSC Construction, Inc. of Simi Valley, California, prepared drilling pads and temporary drilling equipment access routes using a CAT 650 bulldozer. The temporary access routes were limited to approximately 12 feet in width (the approximate width of the largest drilling vehicle used during our investigation). Drilling pad sizes were limited to only allow drilling equipment and support vehicles to access the proposed boring/coring locations. Furthermore, where possible, efforts were made to protect existing vegetation along temporary drilling pad access routes. Where necessary, drilling and construction equipment crossed stream channels only at existing, well-established, unpaved crossings. Such precautions were taken to protect biologically sensitive areas on the subject property, and to minimize surface disturbance throughout the site.

- Large Diameter Bucket-Auger Drilling:

A total of 13 borings were completed using large diameter bucket-auger truck-mounted drill rigs. With the exception to boring KB-10, Tri Valley Drilling of Ventura, California completed the borings. Boring KB-10 was drilled by Big Johnny's & Pam's Drilling of Azusa, California. Boring BA-1 was advanced to a depth of 100 feet below existing grade and down-hole logged by our engineering geologist, Mr. K. Douglas Cook and project geologist, Mrs. Janis Hernandez. Borings KB-1 through KB-12 were advanced to depths of approximately 15 to 100 feet below the ground surface. Borings KB-1 through KB-12 were down-hole logged by our engineering geologist, Mr. K. Douglas Cook and project geologist, Mrs. Janis Hernandez. The cuttings from the borings were placed in the borehole cavities after down-hole logging of the borings was completed.

The Logs of Borings BA-1, and KB-1 through KB-12 are presented as Plates A-2 through A-14. An explanation of the classified soils/bedrock encountered according to the Unified Soil Classification System and Unified Rock Classification System (as applicable) is shown in Plates A-1A and A-1B, respectively. A key to the Log of Boring is presented in Plate A-1C of this appendix. The boring log describes the earth materials encountered, samples obtained, and show field tests performed. The logs also show the boring number, drilling date and the name of the logger and drilling subcontractor. The boundaries between earth material types shown on the logs are approximate because the transition between different soil and/or rock layers may be gradual. Bulk and intact samples of representative earth materials were obtained from the borings.

A California Sampler was used to obtain relatively undisturbed samples of the earth materials encountered. This sampler consists of a 3-inch O.D., 24-inch I.D. split barrel shaft that is driven a total of 12-inches into the soil/weathered rock at the bottom of the boring. The earth materials retained in one (1)-inch brass rings for future laboratory testing. An additional two (2)-inches of soil from each drive remained in the cutting shoe and was usually discarded after visually classifying the soil/weathered rock. The number of blows required to push or drive the sampler 12 inches is presented on the boring logs.

The sampler was driven using a Kelly bar. The effective weight of the Kelly bar varies with depth as follows for each drilling contractor used:

Tri-Valley Drilling:

Depth (feet)	Effective Weight (lb.)
0 to 30	5,952
30 to 57	3,951
57 to 86	2,531
86 to 115	1,407

Big Johnny's & Pam's Drilling:

Depth(feet)	Effective Weight(lb.)
0 to 25	2,500
25 to 45	1,500
45 to 70	750
70 +	1,500

The total number of hammer blows required to drive the sampler the 12 inches is termed the blow count and is recorded on the Logs of Borings. Bulk samples of the surface soils were retrieved directly from the bucket.

- **Continuous Rock Coring:**

A total of six exploratory continuous rock corings (C-1 through C-5, and C-1A) were drilled using a CME-75 truck-mounted drill rig furnished by J.E.T. Drilling, Inc. of Signal Hill, California. Borings C-1 through C-5 and C-1A were advanced to depths ranging between 109 to 274 feet below the existing ground surface. With the exception to coring C-3, all cores were completed by wire-line method using a diamond-tipped core drilling bit (HQ core bit) to obtain relatively undisturbed samples of the earth materials encountered. This system employs a 3.75-inch O.D. core barrel casing within which the retractable diamond-tipped HQ core bit and sampling tube is inserted/extracted. The HQ core bit produces a continuous 2.5-inch diameter rock core sample, in segments of 5 feet (which is equivalent to the length of the sampling tube and core barrel casing segments used).

Coring C-3 was completed by hard line method using a diamond-tipped rock core drilling bit (Nx core bit) to obtain relatively undisturbed samples of the earth materials encountered. This system employs a 3-inch O.D. core barrel casing within which the diamond-tipped Nx core bit and sampling tube is inserted. The Nx core bit produces a continuous 1.75-inch diameter rock core sample, in segments of 5 feet.

Drilling fluids are circulated internally through either core bit to cool cutting surfaces (as a result of friction), provide lubrication during cutting, and lift earth material cuttings out of the core hole along the outer core barrel casing. Following geological classification, the continuous, intact core samples were transferred to partitioned wax-coated cardboard rock sample core boxes, labeled, and photographed both in the field and following transport to the office. The time required to advance the core barrel 5 feet is presented on the coring logs.

Our project geologists, Mr. T. Anthony Harding and Mrs. Janis Hernandez geologically logged the rock core samples in the field. Following drilling activities, the core hole cavities were backfilled using a mixture of CETCO high solids Volclay Grout and CETCO Super Gel-x extra high yield Na-bentonite powder and capped with Na-bentonite medium chips and native soil. At the location of coring C-5, Na-bentonite medium chips were blended with the above noted mixture to prevent coring sealant (fluid) loss.

The Logs of Borings C-1A, and C-1 through C-5 are presented as Plates A-36 through A-41. An explanation of the classified soils/bedrock encountered according to the Unified Soil Classification System and Unified Rock Classification System (as applicable) is shown in Plates A-1A and A-1B, respectively. A key to the Log of Coring is presented in Plate A-1D of this Appendix. The coring log describes the earth materials encountered, structural features encountered, samples obtained, rock quality determinations, core recovery percentage, core drilling rates, and show laboratory tests performed. The logs also show the coring number, drilling date and the name of the logger and drilling subcontractor. The boundaries between earth materials shown on the logs are approximate because the transition between different soil and/or rock layers may be gradual.

TRENCHES AND TEST PIT EXCAVATIONS

Fault trenches and test pits were excavated on site as a part of this investigation. The trenches and test pits were excavated with a rubber-tire Ford 755 backhoe with 24 inch wide bucket, provided by RSC Construction, Inc. and M.F. Excavating of Simi Valley, California. The backhoe equipment and operator was supplied to Kleinfelder by Presidio Group, LLC. Test pits were excavated to identify surface and subsurface features of bedding structure and to review surface lineament features identified during our aerial photograph review. Additionally, several shallow test pits were excavated along the western portion of the site to assist in revealing bedding structure and material anticipated during grading operations.

Fault trenches were excavated for this study to investigate previously mapped lineaments and faults across the site. The trenches and faults were logged by our geologist and reviewed by our engineering geologist. Additionally, photographs were taken of the mapped trenches and test pits for logging documentation. Stakes were left on site at the head and toe of each mapped trench and test pit for later land survey or GPS survey. All test pits, shallow test pit excavations and fault trenches were loosely back-filled with the excavated materials and tamped at the surface with the bucket and driven over with the backhoe tires.

The Logs of Test Pits KP-1 through KP-35 are presented as Plates A-15 through A-35. An explanation of the classified soils/bedrock encountered according to the Unified Soil Classification System and Unified Rock Classification System (as applicable) is shown in Plates A-1A and A-1B, respectively. The test pit logs describe the earth materials encountered, structural features, and includes a scaled cross-sectional view of the test pit identifying features encountered. The logs also show the test pit number, scale used for the cross-sectional view, and the name of the logger, and date excavation activities were performed. The boundaries between earth material types shown on the logs are approximate because the transition between different soil and/or rock layers may be gradual.

NOTES ON FIELD INVESTIGATION

- SAMPLE** - Graphical representation of sample type as shown below.

 - Split Spoon - Standard Penetration Test Sample (SPT)
 - Drive Sample - California Sample (Cal)
 - Bulk Sample - Obtained by collecting cuttings in a plastic bag
 - Tube Sample - Shelby/Pitcher Tube Sample
- SAMPLE NO.** - Sample Number
- BLOWS/FT** - Number of blows required to advance sampler 1 foot (unless a lesser distance is specified). Samplers in general were driven into the soil at the bottom of the hole with a standard (140 lb) hammer dropping a standard 30 inches. Drive samples collected in bucket auger borings may be obtained by dropping non-standard weight from variable heights. When a SPT sampler is used the blow count conforms to ASTM D-1586.

SCR/RQD - Sample Core Recovery (SCR) in percent (%) and Rock Quality Designation (RQD) in percent (%). RQD is defined as the percentage of core in each run which the spacing between natural fractures is greater than 4 inches. Mechanical breaks of the core are not considered.
- GRAPHIC LOG** - Standard symbols for soil and rock types, as shown on plate A-1b.
- GEOTECHNICAL DESCRIPTION**

Soil - Soil classifications are based on the Unified Soil Classification System per ASTM D-2487, and designations include consistency, moisture, color and other modifiers. Field descriptions have been modified to reflect results of laboratory analyses where deemed appropriate.

Rock - Rock classifications generally include a rock type, color, moisture, mineral constituents, degree of weathering, alteration, and the mechanical properties of the rock. Fabric, lineations, bedding spacing, foliations, and degree of cementation are also presented where appropriate.

Description of soil origin or rock formation is placed in brackets at the beginning of the description where applicable, for example, Residual Soil.
- DRY DENSITY, MOISTURE CONTENT:** As estimated by laboratory or field testing.
- ADDITIONAL TESTS** - (Indicates sample tested for properties other than the above):

MAX - Maximum Dry Density	SG - Specific Gravity	PP - Pocket Penetrometer
GS - Grain Size Distribution	HA - Hydrometer Analysis	WA - Wash Analysis
SE - Sand Equivalent	AL - Atterberg Limits	DS - Direct Shear
EI - Expansion Index	RV - R-Value	CP - Collapse Potential
CHEM - Sulfate and Chloride Content, pH, Resistivity	CN - Consolidation	UC - Unconfined Compression
PM - Permeability	CU - Consolidation Undrained Triaxial	T - Torvane
UU - Unconsolidated Undrained Triaxial	CD - Consolidated Drained Triaxial	
- ATTITUDES** - Orientation of rock discontinuity observed in bucket auger boring or rock core, expressed in strike/dip and dip angle, respectively, preceded by a one-letter symbol denoting nature of discontinuity as shown below.

B: Bedding Plane J: Jointing C: Contact F: Fault S: Shear

NOTES ON FIELD INVESTIGATION

- SAMPLE TYPE** - Graphical representation of sample type as shown below.
 Continuous Core - Core retrieved by HQ, N_x core bits. 
 No Recovery - Zone encountered in which a sample was not able to be collected. 
- BOX NUMBER** - Identification number of box containing core
- CORE RECOVERY PERCENT** - Percent of core recovered within a given drilling interval.
- GRAPHIC LOG** - Standard symbols for soil and rock types, as shown on plate A-1b.
- GEOTECHNICAL DESCRIPTION**
Soil - Soil classifications are based on the Unified Soil Classification System per ASTM D-2487, and designations include consistency, moisture, color and other modifiers. Field descriptions have been modified to reflect results of laboratory analyses where deemed appropriate.
Rock - Rock classifications generally include a rock type, color, moisture, mineral constituents, degree of weathering, alteration, and the mechanical properties of the rock. Fabric, lineations, bedding spacing, foliations, and degree of cementation are also presented where appropriate. Includes orientation of rock discontinuities, expressed as strike/dip and dip angle respectively.
 Description of soil origin or rock formation is placed in brackets at the beginning of the description where applicable, for example, Residual Soil.
- ROCK MASS RATING** - Geomechanics classification of rock masses after Z. T. Bieniawski
- ROCK QUALITY DETERMINATION** - Ratio of recovered core sections >4" relative to total recovered core length.
- CORE DRILLING RATE** - Expressed as time (min.) required to drill given interval of length (ft.).

EXPLANATION OF LOGS

PLATE
A-1c

UNIFIED ROCK CLASSIFICATION SYSTEM

PRIMARY DIVISIONS	GROUP SYMBOLS		SECONDARY DIVISIONS	
TYPICAL FORMATIONAL MATERIALS	GRAVELS	GP		POORLY GRADED GRAVELS OR GRAVEL-SAND MIXTURES, LITTLE OR NO FINES
	SANDSTONES	SS		
	SILTY SANDSTONE	SLTSS		
	SANDY SILTSTONE	SSLST		
	SILTSTONES	SLTST		
	CLAYSTONES	CS		
	SHALES	SL		

CLASSIFICATION CRITERIA BASED ON FIELD TESTS

SUGGESTED CLASSIFICATION FOR WEATHERED ROCKS ¹		
Grade	Symbol	Diagnostic Feature
Fresh	F	No visible sign of decomposition or discoloration. Rings under hammer impact.
Slightly weathered	WS	Slight discoloration inward from open fractures, otherwise similar to F.
Moderately weathered	SM	Discoloration throughout. Weaker minerals such as feldspar decomposed. Strength somewhat less than fresh rock, but cores cannot be broken by hand or scraped by knife. Texture preserved.
Highly weathered	WH	Most minerals somewhat decomposed. Specimens can be broken by hand with effort or shaved with knife. Core stones present in rock mass. Texture becoming indistinct but fabric preserved.
Completely weathered	WC	Minerals decomposed to soil but fabric and structure preserved (saprolite). Specimens easily crumbled or penetrated.
Residual soil	RS	Advanced state of decomposition resulting in plastic soils. Rock fabric and structure completely destroyed. Large volume change.

¹After ISRM Working Party (1975)

SUGGESTED HARDNESS CLASSIFICATION FOR INTACT ROCK ¹			
Class	Hardness	Field Test	Strength ¹ mg/cm ²
I	Extremely hard	Many blows with geologic hammer required to break intact specimen	>2000
II	Very hard to hard	Hand-held specimen breaks with hammer end of pick under more than one blow	2000-700 700-250
III	Moderate	Cannot be scraped or peeled with knife, hand-held specimen can be broken with single moderate blow with pick	250-100
IV	Soft	Can just be scraped or peeled with knife. Indentations 1mm to 3mm deep show in specimen with moderate blow of pick	100-30
V	Very soft	Material crumbles under moderate blow with sharp end of pick and can be peeled with a knife, but is too hard to hand-trim for triaxial test specimen.	30-10

¹After ISRM Working Party (1975)

¹Uniaxial compressive strength [Core Logging Comm. (1978)].

ENGINEERING CLASSIFICATION FOR IN-SITU ROCK QUALITY		
RQD, %	Velocity Index	Rock-Mass Quality
90-100	0.80-1.00	Excellent
75-90	0.60-0.80	Good
50-75	0.40-0.60	Fair
50-25	0.20-0.40	Poor
25-0	0-0.20	Very Poor

CEMENTATION

DESCRIPTION	FIELD TEST
Weakly	Crumbles or breaks with handling or slight finger pressure
Moderately	Crumbles or breaks with considerable finger pressure
Very Well	Will not crumble or break with finger pressure

Explanation To Logs On Plate A-1

APPENDIX B LABORATORY ANALYSES

After visual classification of the soil samples in the field, the soil and or rock samples were transported to our laboratory in Diamond Bar, California. The earth materials were classified in accordance with the Unified Soil Classification System and Unified Rock Classification System and a testing program was established. Laboratory tests were performed on representative intact and bulk samples to estimate engineering characteristics of the various earth materials encountered. Testing was performed in accordance with one of the following references:

1. Lambe, T. William, Soil Testing for Engineers, Wiley, New York, 1951
2. Laboratory Soils Testing, U.S. Army, Office of the Chief of Engineers, Engineering Manual No. 1110-2-1906, November 30, 1970
3. ASTM Standards for Soil Testing, latest revisions
4. Uniform Building Code, 1997 edition

LABORATORY MOISTURE AND UNIT WEIGHT DETERMINATIONS

In-situ moisture content and dry unit weight tests were performed on samples collected from the borings in accordance with ASTM Standard Test Method D 2216-92 and D 2937-94, respectively. The results are presented in Table B-1, Moisture Content and Unit Weight.

GRAIN SIZE DISTRIBUTION

The grain size distribution of selected soil samples were evaluated by conducting sieve analyses in general accordance with ASTM Standard Test Method D 422-63. The test results are presented on Plate B-1, Grain Size Distribution.

DIRECT SHEAR

The relative strength characteristics of the subsurface materials were estimated from the results of direct shear tests (ASTM D 3080). Direct shear tests were conducted on relatively

undisturbed samples and on remolded samples. The test results for relatively undisturbed samples are presented on Plates B-2 through B-4 and B-8, Direct Shear Test.

Direct shear tests were also conducted on remolded samples of the encountered soils compacted to approximately 90 percent of maximum dry density as determined by ASTM D 1557 test procedures. The remolded samples were placed in contact with water for at least 24 hours before testing and then sheared under normal loads ranging from approximately 0.5 to 6 KSF. The test results for the remolded samples are presented on Plates B-5 through B-7, Direct Shear Test.

One sample of the siltstone materials, which was prepared by remolding the sample to a wet density of 125 pcf, was saturated and sheared three times to evaluate the along bedding residual shear strength of the siltstone materials. The results of this test are presented on Plate B-9, Direct Shear Test.

CORROSIVITY TESTS

A series of chemical tests were performed by others on selected near surface samples to estimate Soluble Sulfate (California Test Method 417), Soluble Chloride (California Test Method 422) and pH and Resistivity (California Test Method 643). The test results may be used by a qualified corrosion engineer to evaluate the general corrosion potential with respect to the construction materials. The results of the tests are presented in Table B-2, Corrosion Test Results.

MAXIMUM DRY DENSITY

Maximum dry density testing was performed on three selected samples of the near-surface soils encountered at the site. The tests were performed in general accordance with ASTM Standard Test Method D 1557. The test results are presented on Table B-3, Maximum Dry Density and Optimum Moisture Content.

UNCONFINED COMPRESSION TEST

AP Engineering and Testing, Inc performed unconfined compression tests on selected, relatively undisturbed samples of the bedrock core samples. The test results are attached to this appendix. As shown on the stress strain diagram, the peak strength of the material exceeded the capacity of the testing equipment, which is approximately 262 KSF. The tests were performed in general accordance with ASTM Standard Test Method D 2166.

TRIAxIAL COMPRESSION TESTS

AP Engineering and Testing, Inc. performed consolidated undrained (CU) triaxial compression tests on relatively undisturbed samples of the bedrock core samples to evaluate the undrained shear strength of the on site materials. Tests were performed in general accordance with the Army Engineering Manual EM-1110-2-1906, Appendix X. The results of the tests are attached to this appendix. As shown in the attached plots, the peak strengths of the materials exceeded the capacity of the testing equipment.

**APPENDIX C
SLOPE STABILITY ANALYSIS**

GENERAL

In order to assess stability of the fill slopes and the natural sandstone slopes a slope stability analysis was performed on the proposed slopes at the Presidio development. The slopes were analyzed using the computer program XSTABL. XSTABL is a two-dimensional, limit equilibrium analysis to compute the factor of safety for slopes. The program can be used to search for the most critical surface or the factor of safety may be calculated for a specified surface. Failure mechanisms of cut and fill slopes and several repair alternatives for existing and proposed slopes were performed. Table # in our appendix lists all of the analysis performed on the slopes. Plates # to # show the stability analysis sections that were taken.

GEOMETRY OF THE SLOPE AND FAILURE PLANE

The surface topography of the slope to be modeled in XSTABL was obtained from the topographic map prepared by B&E Engineers, Inc. Our geological investigation indicated that the bedding inclination of the sandstone bedrock underlying the slope was both cross and parallel to the slope depending on the location of the profile. All slope stability analysis were performed on proposed sections surface geometry with the exception of Section C-C', P-P', AA-AA' and Q-Q'. We analyzed the stability of these sections for both the existing and proposed slopes since these were all existing landslides.

MATERIAL PROPERTIES

The material properties used in the slope stability analysis are summarized in the table below:

Table C-1

Condition	Moist Density (pcf)	Saturated Density (pcf)	Friction Angle (deg)	Cohesion (psf)
Parallel Bedding	120	130	24.0	150
Cross Bedding	120	130	28.0	4000
Fill Material	120	130	33.0	120
Landslide – Slide Plane	120	130	27	0

These material parameters were arrived at by studying the site geology maps and strike and dip of the Kcs sandstone bedding, boring logs both past and previous, the results from the laboratory tests, and a parametric study of the material parameters. Additionally, Rock Quality Designation (RQD) data and correlations were used in arriving at material parameters for both parallel and cross bedding strengths. The material parameters for the section at C-C', P-P', AA-AA', and Q-Q all of which are existing landslides were arrived at by performing a back analysis approach.

From our analysis we confirmed that the choice of 0 pounds per square foot for the cohesive strength and 27-degrees for the internal angle of friction were appropriate parameters for the slide failure plane for the landslide analysis. The material parameters were estimated by targeting a resulting factor of safety of 1.0. These properties resulted in a factor of safety of 1.0 for all sections.

SLOPE STABILITY ANALYSIS

A series of parametric studies were carried out to bracket the material parameters used in the analysis. Several factors were considered in arriving at these material parameters:

- Stability of the existing slopes
- Material parameters used in previous studies
- Geometry of the existing slope
- Bedding angle whether (parallel or cross)
- Existing landslides
- Laboratory testing and geology
- The analysis was carried out accounting for the parallel versus cross bedding of the existing natural slopes.

Three different search approaches were experimented with to arrive at the most likely failure mechanism for each individual slope section failure surface:

- Circular Failure

- Block Failure
- Specified Failure

When selecting the initiation and termination ranges for the circular and block surface searches initially a wide range of values was prescribed. Several ranges covering the hypothesized critical areas were run to ensure the worst possible failure surface and surface type was selected. Once we were able to narrow down the location of the failure surfaces, we re-ran the analysis to cluster the 10 most critical failure surfaces. There were cases where by using a block failure surface we yielded a lower factor of safety than by using a circular failure surface and vice versa. The results and the factors of safety are discussed in detail in the following sections.

In cases where both circular and block failure surfaces were generated, the failure surface repair was analyzed using the lower of the two failure surfaces also. For the three landslides that were identified in profiles C-C', P-P', AA-AA' and P-P'; all three failure surfaces were generated and the failure surface resulting in the lowest factor of safety was used to arrive at our material parameters.

MATERIAL MODEL AND ANISOTROPY

The conventional Mohr-Coulumb strength envelope was used as the material model within XSTABL. The option of selecting the non-linear Mohr-Coulumb model was not used. We feel due to uncertainties in material parameters and lack of sufficient stress strain behavior of the materials, this level of exactness is not warranted. The conventional Mohr-Coulumb model is a well accepted model and is standard of practice in slope stability analysis.

Anisotropic strengths were assigned to the K_{cs} sandstone bedrock material at the site to capture and account for the directional shear strength due to bedding strike and dip. Cross and parallel bedding shear strength properties were assigned to appropriate zones by studying the orientation. A minimum of 20 degrees angle range was used when assigning the anisotropic strength parameter ranges to account for the variability and uncertainty in the bedding angles.

PSEUDO-STATIC ANALYSIS

As discussed in our seismicity and geology section, this area is known for experiencing earthquakes, and therefore all permanent slopes were analyzed for stability under earthquake loading. We used a pseudo-static approach towards modeling the seismic stability of slopes. In our method of analysis, a horizontal coefficient is applied to the potential slide mass and the factor of safety against slope stability is evaluated. The horizontal coefficient used in our analysis was $K_H=0.15$. We assumed a vertical coefficient, $K_v = 0.0$. The results of the pseudo-static analysis are presented in the results section of this report and are also summarized in TableC-2 in Appendix C.

FACTOR OF SAFETY

It is noted that the factor of safety is defined as the resisting forces divided by the driving forces. Therefore a factor of safety of 1.0 indicates the driving forces equal the resisting forces and the slope is stable. If a slope is safely moving along a slide plane its factor of safety is slightly less than 1.0, say 0.95. Man made fill slopes is usually designed to have a factor of safety of 1.5. All permanent slopes were analyzed to have a minimum static factor of safety of 1.5 and a minimum pseudo-static factor of safety of 1.1. Temporary cut slopes was analyzed to have a minimum factor of safety of 1.5.

Overall RMR Class 13 V Very Poor Rock

This rock exhibits an average standup time of 30 minutes for a 1 meter horizontal span < 100 kPa rock mass cohesion, and a friction angle < 15 degrees.

ASSESSMENT OF THE EXPOSED ROCK SLOPE

Location

The exposed rock slope is located near the town of Chatsworth, CA, and is divided into various rock outcrops across the south side of the Brown's Canyon. Outcrops range in height from less than five feet to approximately 40 feet. Two vertical traverses were completed on the slope to map the exposed rock outcrops located near transection areas F - F' and G - G'. Both traverses started at the crest of the rock slope and traversed to the bottom of Brown's Canyon and the creek bed. Two outcrops were mapped along the traverse through area F - F' and five outcrops were mapped along the traverse through area G - G'.

RMR and Strength

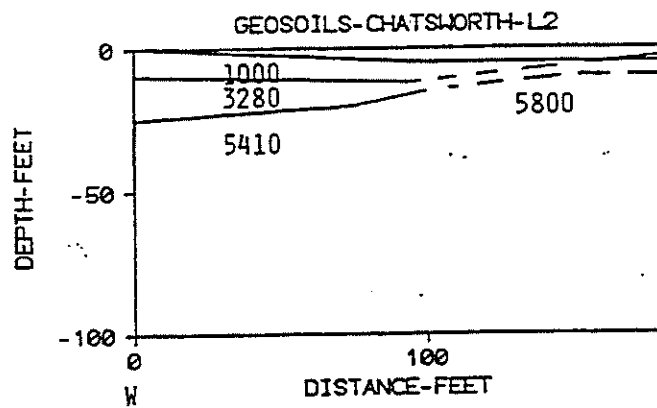

Table 2 provides specific geomechanical data on the rock mass of the outcrops located on the south slope. Based on our assessment, the overall RMR for the south slope is 6, which means the rock mass is composed of very poor quality rock as a whole (Class V). Based on Bieniawski's (1989) RMR tables, Class No. V rock exhibits cohesion of less than 100 kPa (approx. 15 psi), which is less than 2200 psf. Similarly, friction angles for this class of rock are less than 15°. Based on the overall RMR of 6, which is very poor rock, we chose a conservative cohesion and friction angle of 2000 psf and 15°, respectively. Appendix B contains individual RMR tables recorded at locations on the south slope.

In the outcrops, we observed highly weathered medium to coarse grained sandstone. Rock fragments up to cobble size had previously raveled down the slope. Strength of the weathered rock mass, as estimated from field observation and blows by geology hammer, indicates that the sandstone is generally very weak to weak rock (ISRM).

APPENDIX D
SUMMARY OF NATURAL AND PROPOSED SLOPES

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
Natural Slopes			
1 – Natural Slope	Below Lots 173 through 179	1½:1 to 2:1 natural slope	Kcs steeply oriented unfavorably out of slope, toward Browns Canyon
2 – Natural Slope	U-U' Below Lots 166 through 172	1 ½:1 to 1¼:1 natural slope	Kcs bedrock, with interbedded siltstone and some claystone, oriented steeply out of slope
3 – Natural Slope	Below Lots 141 through 144, and 164 through 166	1 ½:1 to 1¼:1 natural slope, small fill slope near “B” Street with 10 foot high retaining wall at the toe	Surficial debris on steep slope faces, Kcs bedrock, with interbedded siltstone and some claystone, oriented unfavorably out of slope, alluvial removals on the order of 3 to 5 feet anticipated
4 – Natural Slope	C-C'	190 Feet high, 280 feet long, 2:1 natural slope.	Slope contains wedge failure and potential block glide landslide. Lots 54 and 55 will be impacted by an existing head scarp and or extreme surficial slope instability. Kcs bedrock is oriented unfavorably out of slope. Recommend 100 foot structural setback restricted use area.
4 – Natural Slope	E-E'	130 Feet high, 240 feet long, 2:1 natural slope.	Kcs bedrock is oriented unfavorably out of slope, apparent dips 10 to 21 degrees
5 – Natural slope	G-G'	100 feet high, 200 feet long, 2:1 or flatter	Slope contains potential block glide landslide. Lots 26 through 29 will be impacted by surficial slope instability. Kcs bedrock oriented unfavorably out of slope, moderately dipping

Slope No. and Type	Cross-Section or General Location	Maximum Slope Height, Length and Inclination	Anticipated Geologic Conditions
6 – Natural Slope	B-B'	100 feet high, 210 feet long (west), 200 feet long (east), 2:1 or flatter near top, 1 ½:1 mid-slope to toe	Lineament from CDMG identified approximately 100 feet east of left (western) bridge abutment, Kcs bedrock is oriented unfavorably out of slope along western slope areas. Eastern slope areas are oriented favorably into slope, moderately to steeply dipping.

APPENDIX F
GENERAL EARTHWORK AND GRADING GUIDELINES

1.0 General Intent

These specifications present general procedures and requirements for grading and earthwork as shown on the approved grading plans, including preparation of areas to be filled, placement of fill, installation of subdrains, and excavations. The recommendations contained in the geotechnical report are a part of the earthwork and grading specifications and shall supersede the provisions contained hereinafter in the case of conflict. Evaluations performed by the consultant during the course of grading may result in new recommendations which could supersede these specifications or the recommendations of the geotechnical report.

1.0 Earthwork Observation and Testing

Prior to the commencement of grading, a qualified geotechnical consultant (soils engineer and engineering geologist, and their representatives) shall be employed for the purpose of observing earthwork procedures and testing the fills for conformance with the recommendations of the geotechnical report and these specifications. It will be necessary that the consultant provide adequate testing and observation so that he may determine that the work was accomplished as specified. It shall be the responsibility of the contractor to assist the consultant and keep him apprised of work schedules and changes so that he may schedule his personnel accordingly.

It shall be the sole responsibility of the contractor to provide adequate equipment and methods to accomplish the work in accordance with applicable grading codes or agency ordinances, these specifications and the approved grading plans. If, in the opinion of the consultant, unsatisfactory conditions, such as questionable soil, poor moisture condition, inadequate compaction, adverse weather, etc., are resulting in a quality of work less than required in these specifications, the consultant will be empowered to reject the work and recommend that construction be stopped until the conditions are rectified.

Maximum dry density tests used to determine the degree of compaction will be performed in accordance with the American Society for Testing and Materials test method ASTM D1557-78.

3.0 Preparation of Areas to be Filled

3.1 Clearing and Grubbing: All brush, vegetation and debris shall be removed or piled and otherwise disposed of.

3.2 Processing: The existing ground which is determined to be satisfactory for support of fill shall be scarified to a minimum depth of 6 inches. Existing ground which is not satisfactory shall be overexcavated as specified in the following section. Scarification shall continue until the soils are broken down and free of large clay lumps or clods and until the working surface is reasonably uniform and free of uneven features which would inhibit uniform compaction.

- 3.3 Overexcavation: Soft, dry, spongy, highly fractured or otherwise unsuitable ground, extending to such a depth that surface processing cannot adequately improve the condition, shall be overexcavated down to firm ground, approved by the consultant.
- 3.4 Moisture Conditioning: Overexcavated and processed soils shall be watered, dried-back, blended, and/or mixed, as required to attain a uniform moisture content near optimum.
- 3.5 Recompaction: Overexcavated and processed soils which have been properly mixed and moisture-conditioned shall be recompacted to a minimum relative compaction of 90 percent.
- 3.6 Benching: Where fills are to be placed on ground with slopes steeper than 5:1 (horizontal to vertical units), the ground shall be stepped or benched. The lowest bench shall be a minimum of 15 feet wide, shall be at least 2 feet deep, shall expose firm material, and shall be approved by the consultant. Other benches shall be excavated in firm material for a minimum width of 4 feet. Ground sloping flatter than 5:1 shall be benched or otherwise overexcavated when considered necessary by the consultant.
- 3.7 Approval: All areas to receive fill, including processed areas, removal areas and toe-of-fill benches shall be approved by the consultant prior to fill placement.

4.0 Fill Material

- 4.1 General: Material to be placed as fill shall be free of organic matter and other deleterious substances, and shall be approved by the consultant. Soils of poor gradation, expansion, or strength characteristics shall be placed in areas designated by the consultant or shall be mixed with other soils to serve as satisfactory fill material.
- 4.2 Oversize: Oversize material defined as rock, or other irreducible material with a maximum dimension greater than 12 inches, shall not be buried or placed in fills, unless the location, materials, and disposal methods are specifically approved by the consultant. Oversize disposal operations shall be such that nesting of oversize material does not occur, and such that the oversize material is completely surrounded by compacted or densified fill. Oversize material shall not be placed within 10 feet vertically of finish grade or within the range of future utilities or underground construction, unless specifically approved by the consultant.
- 4.3 Import: If importing of fill material is required for grading, the import material shall meet the requirements of Section 4.1.

5.0 Fill Placement and Compaction

- 5.1 Fill Lifts: Approved fill material shall be placed in areas prepared to receive fill in near-horizontal layers not exceeding 6 inches in compacted thickness. The consultant may approve thicker lifts if testing indicates the grading procedures are such that adequate compaction is being achieved with lifts of greater thickness. Each layer shall be spread evenly and shall be thoroughly mixed during spreading to attain uniformity of material and moisture in each layer.
- 5.2 Fill Moisture: Fill layers at a moisture content less than optimum shall be watered and mixed, and wet fill layers shall be aerated by scarification or shall be blended with drier material. Moisture-conditioning and mixing of fill layers shall continue until the fill material is at a uniform moisture content at or near optimum.

- 5.3 Compaction of Fill: After each layer has been evenly spread, moisture-conditioned, and mixed, it shall be uniformly compacted to not less than 90 percent of maximum dry density. Compaction equipment shall be adequately sized and shall be either specifically designed for soil compaction or of proven reliability, to efficiently achieve the specified degree of compaction.
- 5.4 Fill Slopes: Compacting of slopes shall be accomplished, in addition to normal compacting procedures, by backrolling of slopes with sheepfoot rollers at frequent increments of 2 to 3 feet in fill elevation grain, or by other methods producing satisfactory results. At the completion of grading, the relative compaction of the slope out to the slope face shall be at least 90 percent.
- 5.5 Compaction Testing: Field tests to check the fill moisture and degree of compaction will be performed by the consultant. The location and frequency of tests shall be at the consultant's discretion. In general, the tests will be taken at an interval not exceeding 2 feet in vertical rise and/or 1,000 cubic yards of embankment.

6.0 Subdrain Installation

Subdrain systems, if required, shall be installed in approved ground to conform to the approximate alignment and details shown on the plans or herein. The subdrain location or materials shall not be changed or modified without the approval of the consultant. The consultant, however, may recommend and upon approval, direct changes in subdrain line, grade or material. All subdrains should be surveyed for line and grade after installation and sufficient time shall be allowed for the surveys, prior to commencement of filling over the subdrains.

7.0 Excavation

Excavations and cut slopes will be examined during grading. If directed by the consultant, further excavation or overexcavation and refilling of cut areas shall be performed, and/or remedial grading of cut slopes shall be performed. Where fill-over-cut slopes are to be graded, unless otherwise approved, the cut portion of the slope shall be made and approved by the consultant prior to placement of materials for construction of the fill portion of the slope.

APPENDIX G
PRELIMINARY BRIDGE FOUNDATION RECOMMENDATIONS

SEISMIC DESIGN

Faulting

The site is not within a current Alquist-Priolo Earthquake Fault Zone. The nearest mapped fault trace is the Simi-Santa Rosa-Northridge Hills fault. It passes less than 1 km to the north of the subject bridge sites. According to Mualchin (1996), the Simi-Santa Rosa-Northridge Hills fault is a reverse oblique fault.

The shortest distance from the site to the above mentioned fault and other major active fault systems and their maximum earthquake magnitudes are presented in Table 7-1. The locations of the faults and associated parameters presented on Table 7-1 are based on data presented by Working Group on California Earthquake Probabilities (1995), Jennings (1994), Mualchin (1996), Petersen et. al. (1996), and Frankel et. al. (1996).

SEISMIC DESIGN CRITERIA

The following seismic design parameters may be used for the preliminary design of the Presidio bridges in Chatsworth, California. These values were estimated using the California Seismic Hazard Map 1996 (Mualchin, 1996) and procedures outlined in Caltrans Seismic Design Criteria (SDC) Version 1.1 (1999). Based on the results of our field investigation, the subsurface soils mainly consist of thin layer of alluvium over sandstone. Therefore, we have classified the Soil Profile Type as B.

The data used in developing the ARS curve are presented in Table 7-2. The ARS Curve presented in Figure B.2 of the Caltrans Seismic Design Criteria (SDC) for 0.6g was modified according to the guidelines presented in Section 6.1.2.1 of the SDC and Section 3.7 of Caltrans Guidelines for Foundation Investigation and Reports to develop the recommended ARS Curve. Because the structure is within 15 km of an active fault and the fault is a reverse - oblique fault, we modified the ARS curve as follows:

- Increased the spectral acceleration on the ARS curve by 10 percent for periods below 0.5 second
- Increased the spectral acceleration on the ARS curve by 20 percent for periods greater than 1 second
- Linearly interpolated spectral acceleration on the curve in increments of 10 to 20 percent between period ½ and 1 second

**TABLE G-2
SEISMIC DESIGN RECOMMENDATIONS**

Condition	Design Recommendation and Reference
Controlling Fault	Simi-Santa Rosa-Northridge Hills fault (Mualchin, 1996)
Type of Fault	Reverse Oblique (Mualchin, 1996)
Site Distance from the Fault	1 km (Mualchin, 1996)
Earthquake Magnitude	7 ½ (Mualchin, 1996)
Peak Acceleration	0.7g (Mualchin, 1996)
Soil Profile Type	B (Table B.1, 1999 Caltrans Seismic Design Criteria)
Base ARS Curve	Figure B.2 (1999 Caltrans Seismic Design Criteria)

LIQUEFACTION EVALUATION

As discussed in Section 3.3, liquefaction generally is not likely other than in saturated alluvium within the creeks and drainages. Foundations for bridge piers within Devil Canyon Creek at the "A" Street structure will be designed considering liquefaction of the surficial soils.

SCOUR EVALUATION

We recommend conducting a scour evaluation for design of bridge piers for any piers located within the flow line of the creek. The effects of potential scour that are subsequently presented in a hydrology or hydraulics report will be incorporated into the bridge foundation design.

CORROSION EVALUATION

No corrosion data has been obtained for this preliminary evaluation. The final bridge design will require corrosion testing of surface water and soils to evaluate potential soil corrosivity issues.

PRELIMINARY FOUNDATION RECOMMENDATIONS

Subsurface Conditions

We evaluated the proposed bridge foundations based upon the sandstone materials we encountered in our borings. Our limited laboratory testing on samples of the sandstone in boring

KB-4 indicate friction angles of 53 to 61 degrees and cohesion values ranging from 160 to 1,870 psf. Water was not encountered in the borings drilled near the proposed abutment locations, however surface water is likely to be encountered at the pier locations.

Foundations

We anticipate the bridge foundations may be supported either on spread footings or cast-in-drilled-hole (CIDH) piles. Driven piles are not recommended because of the dense bedrock formations on site. Because of the high seismicity at the site, spread footings may not be able to develop adequate lateral and uplift resistance, in which case CIDH pile foundations would be necessary. Large capacity CIDH piles may be desired in order to limit the number of piles required for structure support.

Design recommendations for CIDH piles are based upon the structural loads (demands), and various lengths and diameters can be evaluated to optimize the foundation design for both cost and performance. These items will be coordinated closely with the structural engineer during the design phase. Various diameters and lengths can be designed to resist the applied loads, and lateral demands may control the recommended shaft lengths. We recommend minimum CIDH pile lengths of 20 feet, and minimum diameters of 24 inches. The actual shaft lengths and diameters will be designed based upon the axial (downward and upward) and lateral demands, with considerations for scour and liquefaction included in the design lengths.

We performed preliminary evaluations of allowable bearing capacity for spread footings founded directly on undisturbed sandstone bedrock. Abutment footings founded at least 4 feet below lowest adjacent grade, at least 5 feet wide, and more than 20 feet long may be designed using a net allowable bearing capacity of 10 kips per square foot. Sliding resistance of abutment footings can be evaluated using a friction factor of 0.45 for mass concrete on the silty sandstone bedrock. Shear keys may also be considered for added passive earth pressure to resist lateral movement. Preliminary earth pressures for design are presented in the following section.

Earth Pressures

The information in this section is for abutment walls and footings, and is based on an excavation behind the abutment that is subsequently backfilled with non-expansive engineered fill.

**TABLE G-3
LATERAL EARTH PRESSURES FOR DESIGN**

Earth Pressure Condition	Equivalent Fluid Pressure (lb/ft³)
Active Earth Pressure	36
Seismic Active Earth Pressure	33
Passive Earth Pressure	360

The earth pressures provided in Table 7-3 were calculated assuming vertical walls with horizontal backfill, backfilled with materials that meet Caltrans standards for abutment fills. Proper drainage should be designed behind the walls to allow for drained conditions in the backfill soils and to prevent excessive hydrostatic pressure above the water table, in accordance with Caltrans Standard Plan BO-3 (Caltrans, 1992a).

According to ATC-32 (1996) page 100, it can be assumed that abutment structural backfill will provide an ultimate passive resistance of 7.7 kips per square foot (ksf) for abutment walls with heights greater than or equal to 8 feet. For abutment walls that are less than 8 feet in height, a reduced ultimate passive resistance value of 7.7 ksf multiplied by $(H/8)$ should be used, where H = wall height in feet. A lateral wall movement of 1% of the wall height can be assumed to mobilize the full ultimate passive resistance.

For the seismic earth pressure calculations, the Mononabe-Okabe relationship was used (Seed and Whitman, 1970). Effective horizontal ground acceleration used in the analysis was 0.35g, which is equal to one-half of the peak ground acceleration of 0.7g that we recommend using for design (FHWA, 1986). It should be noted that the seismic earth pressure is an inverted triangle, with the largest earth pressure occurring at the top of the abutment wall. The resultant seismic earth pressure force is applied at approximately 0.6H from the bottom of the wall, where H is the wall height.

Soil in front of and behind abutment walls should consist of low expansive materials with an expansion index (EI) of less than 51. The low EI material should be within a 1:1 slope from outside the heel of the abutment footings.

Construction Considerations

Difficult site access and difficult drilling should be anticipated, resulting in accordingly priced mobilization and drilling costs. At this time, groundwater is not anticipated in the abutment excavations, but may be encountered in the CIDH piles drilled at the pier locations. If groundwater is encountered, the piles should be installed using a synthetic slurry. In addition, if the CIDH piles are constructed under slurry, we recommend conducting non-destructive testing of the completed shafts to check for construction defects.

Additional Field Work and Laboratory Testing

We recommend conducting additional soil/rock borings at the final plan locations of the proposed bridge abutments and piers for the structures. Laboratory testing consisting of corrosivity of soil and surface water should be conducted, as well as unconfined compression tests on retrieved rock core samples.

Review of:

Tentative Map (Tract) Dated By Regional Planning 2/21/01
Previous review sheet dated 7/15/00

ACTION:

Tentative Map feasibility is not recommended for approval.

REMARKS:

As Previously Requested:

1. Provide a geotechnical update report/letter which specifically addresses and evaluate the latest tentative tract map submitted through the Department of Regional Planning.
2. Provide a geotechnical map which is based upon the latest tentative map.
3. Provide static and seismic slope stability analyses for the natural slopes steeper than a 2:1 gradient. Also, provide a geotechnical cross section, for each section analyzed, showing the critical failure plane used in the analyses. Indicate the various shear strength parameters used in the analyses, in the appropriate segments of each failure plane. Show locations of the cross sections used in slope stability analyses on the geotechnical map. Recommend mitigation if factors of safety are below County minimum standards. Recommend mitigation if factors of safety are below County minimum standards or designate as "Restricted Use Area".
4. Address the depth of the unsuitable alluvial soils located within the tract boundaries. Unsuitable alluvial soils deeper than a depth of 5 feet must be designated as "Restricted Use Area".
5. Address the potential for debris flows impacting the proposed development. Recommend mitigation as necessary.
6. The latest tentative map indicates approximately 953,600 cubic yards of material to be exported to a future development site. Address and evaluate where this fill will be placed. Provide a site plan showing this proposed grading and provide specific recommendations as necessary.
7. Provide chemical test results (sulfate, chloride, resistivity, and pH, etc.) for the on-site soils to address the presence of chemicals deleterious to construction materials and utility lines. Recommend mitigation as necessary.

TENTATIVE MAP DATED 2/21/01
ADDRESS north end of Canoga Ave. at 118 Freeway
LOCATION Chatsworth
REPORT DATE 4/24/00
REPORT DATE 4/24/00

The Regional Planning Commission, developer and engineer are advised that:

PRIOR TO RECOMMENDING APPROVAL OF TENTATIVE TRACT OR MINOR LAND SUBDIVISION MAP:

- Revised engineering geologic reports will be required to evaluate the feasibility of the proposed subdivision considering the addition of the 13-acre parcel to the west and the 125-acre parcel to the north of the original 96-acre project.
- A soils report will be required to evaluate the feasibility of the proposed subdivision.
- Sufficient evidence must be submitted to show that the sustained use of private sewage disposal system is possible without inducing a geologic hazard. The Health Department and developer are advised that geologic conditions within this tract may severely limit or prohibit the use of private sewage disposal system that will introduce water into the subsurface.
- Based on the State of California Seismic Hazard Maps, Oat Mountain Quadrangle, the subject site is located in an area with a potential for liquefaction. The above requested engineering geology and soils engineering reports must address the potential for liquefaction and ground failure. Please refer to the attached Materials Engineering Division's "Interim Geology Review Guidelines for Ground Failure/Liquefaction" (GS045 Rev. 5/18/99). Provide this office with two (2) original copies of the reports for review and distribution to the State of California Division of Mines and Geology.
- Based on the State of California Seismic Hazard Maps, Oat Mountain Quadrangle, the site is located in an area with a potential for seismically-induced landslides/slope failure. The above requested engineering geology and soils engineering reports must address the potential for seismically induced slope instability at the subject site. Provide geologic cross sections for all slopes in question and perform seismic slope stability analyses to determine the static and pseudostatic factors of safety. Show the locations of all geologic cross sections used in slope stability analyses on the geologic map. Recommend mitigation if factors of safety are below County minimum standards.
- Comply with remarks/conditions of approval on the attached Soils Engineering Review Sheet dated 3/21/01.

NOTE: Provide a copy of this review with your resubmittal.

APPENDIX K

DRAINAGE CONCEPT & WATER REFERENCE DOCUMENTS

Hydrology Definitions

Best Management Practice (BMP): In water pollution control, the best means available to control pollution of waterways from non-point sources, as opposed to best available technology, which applies to pollution control for point sources.

Burned and Bulked Runoff (Q_{bb}): Runoff from burned areas that is laden with burned vegetation, fines, rocks, and other debris.

Capital Flood (Q_{cap}): The runoff resulting from a theoretical storm based on Los Angeles County Department of Public Works methodology. The "model" storm is derived from 50-year frequency rainfall values which occur in a time sequence patterned after actual major extra-tropical storms occurring in the Los Angeles Region. The calculations of runoff are also based on the soil types and amount of impervious surfaces in a watershed area, and on the assumption that undeveloped portions of the watershed are burned, resulting in significant amounts of debris and sediment being added to the runoff.

Catch Basin: A precast concrete structure installed within a street gutter and under the curb to "catch" surface storm water runoff and convey it to an underground storm drain structure.

Clear Runoff (Q_c): Clear runoff that is absent of fines, rocks, vegetation, and other debris

Closed Drainage System: A series of covered or enclosed drainage conduits used to convey storm runoff. Proposed in lower elevations of the tributary drainage courses wherever least development runoff flows would be less than 2,000 cubic feet per second.

Coefficient of Runoff: A variable in the rational runoff formula which is dependent upon soil type, rainfall intensity, and the percent of imperviousness.

Debris Basin: A basin designed to trap sediment and debris from runoff before the runoff is discharged.

Desilting Basin: A basin planted with grasses, shrubs, or other vegetation and a corrugated metal standpipe used to reduce the velocity of incoming storm flows long enough to allow silt and other debris to settle out of the flowing water before the water is discharged downstream.

Detention Basin: A basin in which storm flows are captured and stored and, therefore, not available for producing surface runoff.

Erosion: The wearing away of land surfaces by water, wind, and ice, or by gravity.

Impervious: A substance that will not permit water to flow through it.

Infiltration: Downward entry of water into soil.

Interception: That portion of precipitation intercepted by vegetation. Intercepted precipitation is disposed of by drip, stem flow, or evaporation (or sometimes sublimation, in the case of snow, sleet, hail, or freezing rain).

Open Drainage System: A series of uncovered or unenclosed drainages devices used to convey storm runoff. Proposed in lower elevations of the tributary drainage courses wherever least development runoff flows would exceed 2,000 cubic feet per second.

Q: Peak runoff measured in cubic feet per second.

Drainage Concept

Standard Urban Storm Water Mitigation Plan (SUSMP)

EIR Case No. 99-239

Project is located Northeast of the intersection of Topanga Canyon Blvd. and the Simi Valley Freeway in the Unincorporated Chatsworth area of the County of Los Angeles.

The majority of the site drains into Devil Canyon watershed area in a southeasterly direction where it discharges into Brown Canyon further downstream of the project.

A small watershed area drains in a southwesterly direction into an existing 30" CMP, Caltrans drainage system, crossing the Simi Valley Freeway.

Proposed development of the project will maintain a similar drainage pattern as the current existing drainage pattern. This means that the total area draining into Devil Canyon and Brown Canyon will be the same in pre- and post-developed conditions. Therefore, no water diversion is anticipated.

Bulked and Burned flow for a 50-year storm is calculated for the undeveloped site conditions (i.e., existing conditions), while Clear flow is calculated for the developed site conditions, (i.e. after project completion), per LA County design criteria.

Several elevated and desilting inlets are proposed along the northerly Project Boundary to intercept debris from upstream watershed.

These inlets will eliminate the Bulk and Burned conditions within the project boundary and therefore reduce the overall amount of bulked and burned flow currently discharged to Devil Canyon. Approximately 4,590 CY of debris will also be eliminated.

LA County Flood Control District—Brown's Canyon Capital Flood Chart indicates a total flow of 9,070 cfs (bulk) and 14,320 cfs (bulk and burn) at Devil Canyon.

This Report includes Drainage Concept studies as follows:

- 1- Existing drainage conditions for the undeveloped site
- 2- Proposed drainage improvements for the project
- 3- Devil Canyon Water Surface Profile
- 4- Capacity of Existing 30" CMP

The following information is used in the Drainage Concept:

- Rainfall Zone "L"
- Soil No 065
- Debris Production Area DPA – 4
- Design Frequency 50-YR
- Debris Production Rate 106 CY / AC
- Bulking Factor 1.66

Proposed project will be designed and constructed in compliance with National Pollutant Discharge Elimination System (NPDES) permit and all applicable State and Local Water Quality permits.

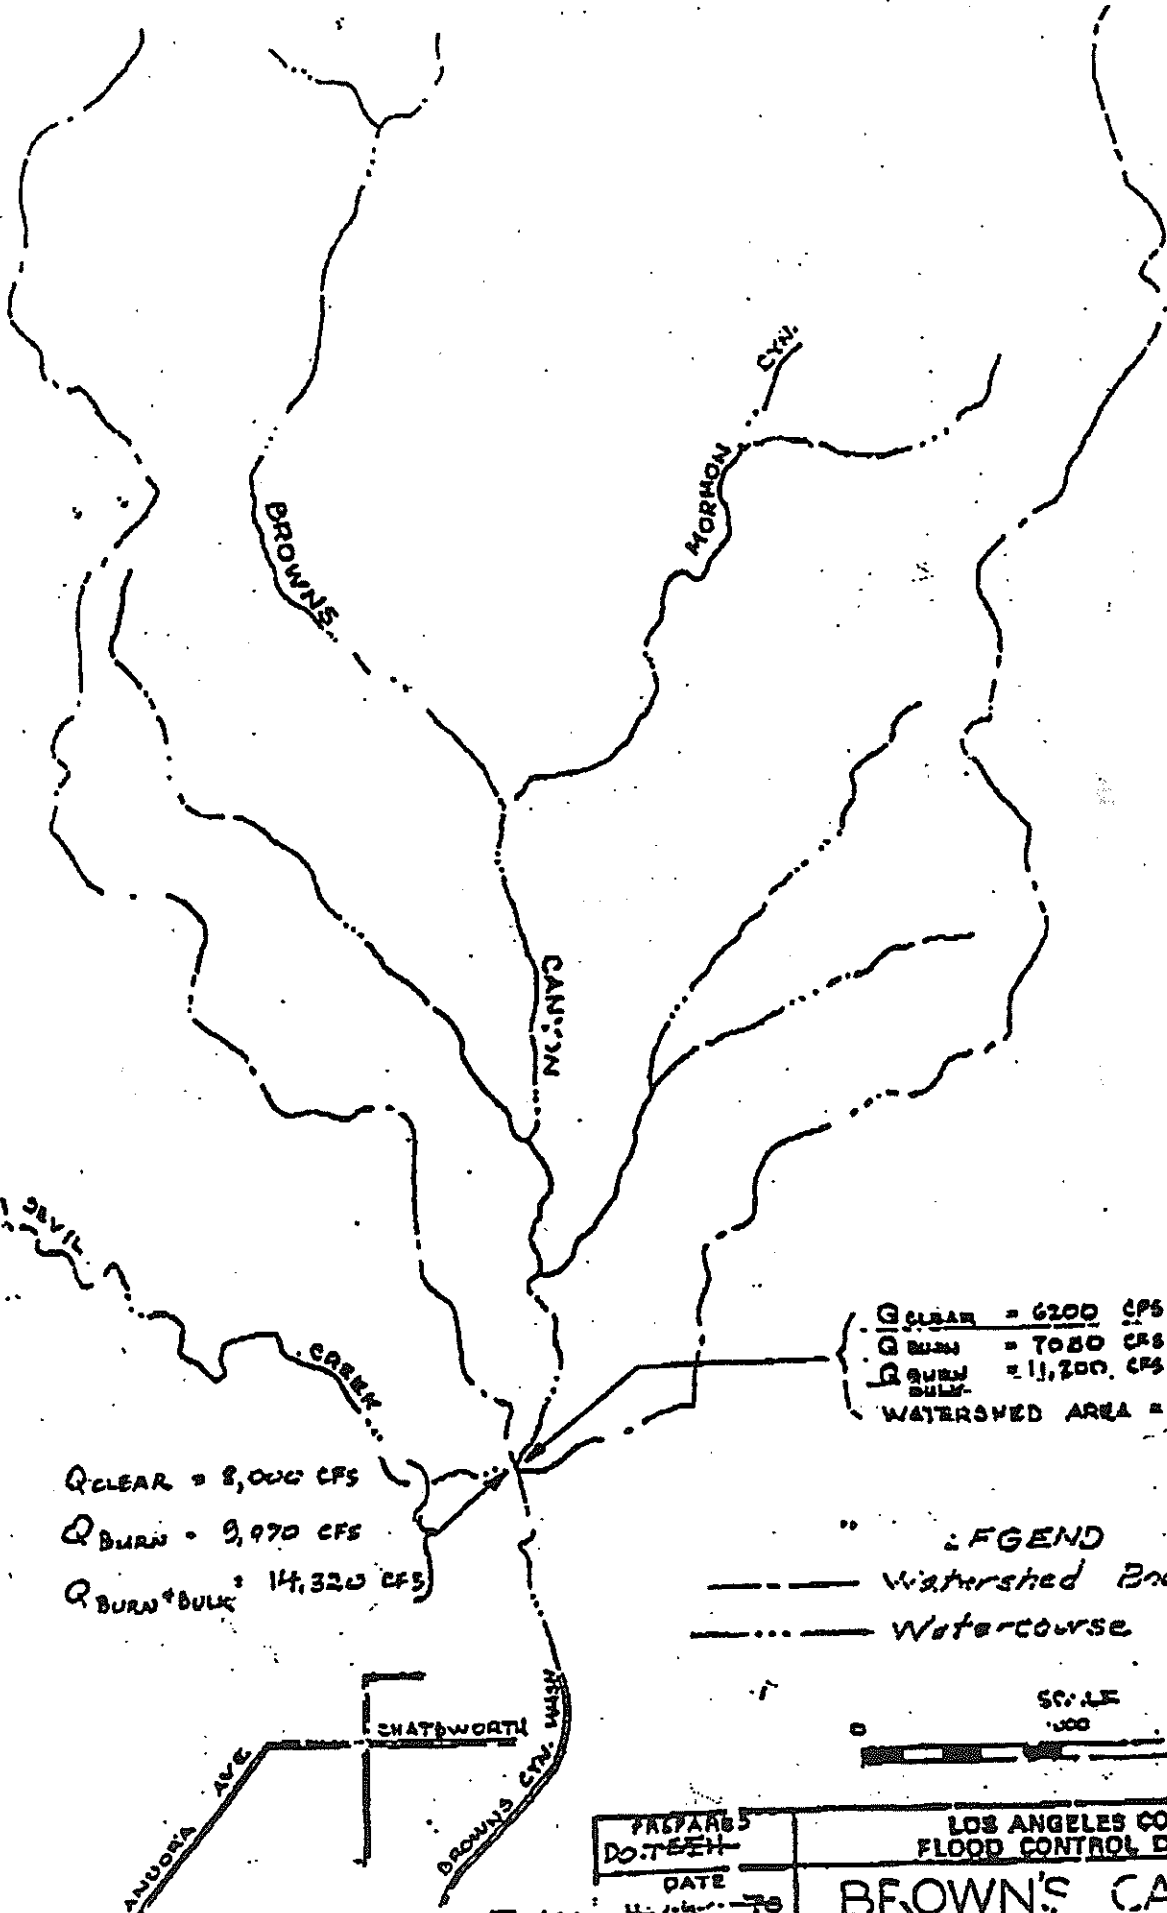

Storm Water Pollution Prevention Plan (SWPPP) and Standard Urban Storm Water Mitigation Plan (SUSMP) will be developed for this site utilizing Best Management Practices (BMP's) for the project.

SWPPP will identify any pollutant sources that may affect quality of storm water discharges during construction. It will implement various pollution prevention measures such as erosion control, dust control and will provide BMP guide to contractors during various stages of site construction

SUSMP will identify any pollutant sources that may affect quality of storm water discharges after project is completed. It will implement various pollution prevention measures including some or all of the following measures:

- Inserts in catch basins and continuous deflection units (CDU) to filter storm water run off prior to discharging to the ocean storm drain system. Sample CDU and filter are shown on enclosed drainage concept map.

$Q_{CLEAR} = 8,000$ CFS
 $Q_{BURN} = 9,970$ CFS
 $Q_{BURN+BULK} = 14,320$ CFS

$Q_{CLEAR} = 6200$ CFS
 $Q_{BURN} = 7080$ CFS
 $Q_{BURN+BULK} = 11,200$ CFS
 WATERSHED AREA = 5.15 MI.²

2	Nat.Mtn	0	0-0	174	.000	.279	.0	1520.0	1340.0	.0	.00	0	0

Code Definitions:

Minimum Conveyance Code: 0=no limits

1=street flow maximum at property line

2=pipe maximum size at 8 feet

3=both 1 and 2 apply

Fixed value code: S=size : 0=fixed size is a minimum drain size

1=fixed size is the exact drain size

X=ext.Q: 0=Urban Design ext. Q varies with frequency.

1=Urban Design external Q is constant.

Strt No.: Street Cross-Section No. - See Street-Cross-Section Data list.

Junct No.: Reach No. junctioning with top of this reach.

Lateral Design Q's:

Design Q's for laterals are calculated separately using a local Time of concentration. Those lateral Q's calculated with the Main Line are for in Line Q development only and not for lateral design Q purposes.

Lot or Overland Flow Data:

Length (ft.)	Elevation (ft) Top	Elevation (ft) Bottom	Slope	Manning's N	Soil No.	Proportion Impervious
200.0	1581.9	1520.0	.310	.060	174	.000

1. TERMINATE WALL AT LOCATIONS WHERE FLOWS RUN ACROSS THE EQUESTRIAN TRAIL. CONSTRUCT TRANSITION DITCHES AT THESE LOCATIONS TO DIRECT FLOWS INTO DRAINAGE BASINS OR OUTLET.

2. DRAINAGE WALL AT TOP OF EQUESTRIAN TRAIL. SLOPE MAY BE REQUIRED AT LOCATIONS MENTIONED ABOVE TO PREVENT RUNOFF SPILLING INTO LOTS BELOW.

INCLUDES BULKED FLOW

- DRAINAGE CONCEPT NOTES:**
- HYDROLOGY INFORMATION AND STORM DRAIN ALIGNMENTS SHOWN ARE NOT NECESSARILY APPROVED.
 - COMPLIANCE OF ALL STREET DRAINAGE REQUIREMENTS WILL BE MET TO THE SATISFACTION OF THE DEPARTMENT OF PUBLIC WORKS.
 - NECESSARY EASEMENTS WILL BE DEPOSITED FOR THE STORM DRAIN SYSTEM TO THE SATISFACTION OF THE DEPT. OF PUBLIC WORKS.
 - ACCESS WILL BE PROVIDED TO ALL WEETS AND OUTLETS TO THE SATISFACTION OF THE DEPARTMENT OF PUBLIC WORKS.
 - APPROVAL OF THE CONCEPT DOES NOT CONSTITUTE DETERMINATION THAT THE DESIGN REQUIREMENTS ARE REQUIRED WITHIN THE MEANING OF GOVERNMENT CODE SECTION 64623. (EXCEPT AS NOTED).
 - A NOTE OF FLOOD HAZARD WILL BE REQUIRED WHERE INDICATED ON THIS PLAN.

NOTE: ALL CROSS DRAINAGE SHALL BE MAINTAINED BY HOMEOWNERS ASSOCIATION. ALL LANDMARKS, CURBS, AND SIGNAGE SHALL BE MAINTAINED BY H.A.A.

LOCAL WATERSHED AREA

LOCATION POINT	EXISTING CONDITION	DEVELOPED CONDITION	FUTURE DIV. OF UPLAND AREA
A	317AC	317AC	118.8 AC
B	876 cfs	458 cfs	50 ACES

* * * ON SHOWN ARE BASED ON THE DEVELOPED AREA OF 118.8 AC. OUT OF THE TOTAL LOCAL WATERSHED AREA OF 317 AC. EXISTING CONDITION O REPRESENTS BURNED AND BULKED O.

HEADWATER DEPTH CALCULATIONS AT DAM

1. ASSUME 48" ϕ OPENING ; $A = 12.57 \text{ ft}^2$
 $V = 14320 / 12.57 = 1139.22 \text{ FPS}$
 $h_v = \frac{1139.22^2}{2 \cdot 32.2} = 20.152 \text{ ft} > 32.5 \text{ ft}$
 \therefore FLOW WILL OVERTOP THE DAM .

2. CALCULATE OVERFLOW OVER THE DAM WITH BROAD-CRESTED WEIR FORMULA .

a) $L = 130 \text{ ft}$, $C = 2.80$

$$Q = CLH^{3/2} ; H = \left[\frac{Q}{CL} \right]^{2/3}$$

$$H = \left[\frac{14320}{2.80(130)} \right]^{2/3} = 11.57 \text{ ft}$$

WATER SURFACE ABOVE TOP OF DAM NEGLECTING THE 48" ϕ OPENING

- b) BY TRIAL AND ERROR , CALCULATE Q_s PASSING OVER THE DAM AND 48" OPENING .

TRY $H = 6.9'$

W.S. EL. OVER DAM = $1162.7 + 6.9 = 1169.6$

$Q_1 = 2.8 \times 249 \times (6.9)^{3/2} = 12637 \text{ CFS}$

FOR 48" ϕ OPENING;

$h_L = 1169.6 - 1140.2 = 29.4'$

$S_f = 29.4/20 = 1.47$

$Q_2 = \frac{1.486}{0.013} (1) (1.47)^{5/2} (12.57) = 1742 \text{ CFS}$

$Q_1 + Q_2 = 12637 + 1742 = 14379 \text{ CFS} > 14320 \text{ CFS}$
NO GOOD

TRY $H = 6.88'$

W.S. EL. OVER DAM = $1162.7 + 6.87 = 1169.58$

$Q_1 = 2.8 \times 249 \times (6.88)^{3/2} = 12581 \text{ CFS}$

FOR 48" ϕ OPENING:

$h_L = 1169.58 - 1140.2 = 29.38'$

$S_f = 29.38/20 = 1.469$

$Q_2 = \frac{1.486}{0.013} (1) (1.469)^{5/2} (12.57) = 1741 \text{ CFS}$

$Q_1 + Q_2 = 12581 + 1741 = 14322 \text{ CFS} \leq 14320 \text{ CFS}$
OK

$1.2h_{v_c} = 1.2(1.66) = 1.99'$

$HW = D_c + 1.2h_{v_c} = 2.26 + 1.99 = 4.25' < 9.1' \text{ o.k.}$

Hydrology Definitions

Best Management Practice (BMP): In water pollution control, the best means available to control pollution of waterways from non-point sources, as opposed to best available technology, which applies to pollution control for point sources.

Burned and Bulked Runoff (Qbb): Runoff from burned areas that is laden with burned vegetation, fines, rocks, and other debris.

Capital Flood (Qcap): The runoff resulting from a theoretical storm based on Los Angeles County Department of Public Works methodology. The "model" storm is derived from 50-year frequency rainfall values which occur in a time sequence patterned after actual major extra-tropical storms occurring in the Los Angeles Region. The calculations of runoff are also based on the soil types and amount of impervious surfaces in a watershed area, and on the assumption that undeveloped portions of the watershed are burned, resulting in significant amounts of debris and sediment being added to the runoff.

Catch Basin: A precast concrete structure installed within a street gutter and under the curb to "catch" surface storm water runoff and convey it to an underground storm drain structure.

Clear Runoff (Qc): Clear runoff that is absent of fines, rocks, vegetation, and other debris

Closed Drainage System: A series of covered or enclosed drainage conduits used to convey storm runoff. Proposed in lower elevations of the tributary drainage courses wherever least development runoff flows would be less than 2,000 cubic feet per second.

Coefficient of Runoff: A variable in the rational runoff formula which is dependent upon soil type, rainfall intensity, and the percent of imperviousness.

Debris Basin: A basin designed to trap sediment and debris from runoff before the runoff is discharged.

Desilting Basin: A basin planted with grasses, shrubs, or other vegetation and a corrugated metal standpipe used to reduce the velocity of incoming storm flows long enough to allow silt and other debris to settle out of the flowing water before the water is discharged downstream.

Detention Basin: A basin in which storm flows are captured and stored and, therefore, not available for producing surface runoff.

Erosion: The wearing away of land surfaces by water, wind, and ice, or by gravity.

Impervious: A substance that will not permit water to flow through it.

Infiltration: Downward entry of water into soil.

Interception: That portion of precipitation intercepted by vegetation. Intercepted precipitation is disposed of by drip, stem flow, or evaporation (or sometimes sublimation, in the case of snow, sleet, hail, or freezing rain).

Open Drainage System: A series of uncovered or unenclosed drainages devices used to convey storm runoff. Proposed in lower elevations of the tributary drainage courses wherever least development runoff flows would exceed 2,000 cubic feet per second.

Q: Peak runoff measured in cubic feet per second.

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
LOS ANGELES REGION

STAFF REPORT AND RECORD OF DECISION
STANDARD URBAN STORM WATER MITIGATION PLANS
AND
NUMERICAL DESIGN STANDARDS FOR BEST MANAGEMENT PRACTICES

SUPPLEMENT

BOARD DIRECTED CHANGES

The Regional Board at its January 26, 2000, meeting directed the Regional Board Executive Officer to amend the Standard Urban Storm Water Mitigation Plans (SUSMPs) as indicated by the change sheet presented at the meeting (dated January 25, 2000), and changes directed by the Regional Board during the meeting. The Regional Board also adopted the same SUSMP requirements for the City of Long Beach under its separate municipal storm water permit (Board Order No. 99-060) for project categories that require SUSMPs.

Regional Board Counsel designated the record for the proceeding to include: (i) all staff files and the transcript of proceedings for the January 26, 2000, Hearing; (ii) all staff files and transcript of proceedings for the September 16, 1999, Board Information Item Discussion; (iii) all staff files for the August 10, 1999, Workshop, (iv) all SUSMP Proposals circulated by the Permittees, (v) all SUSMP Proposals circulated by the Regional Board Staff, (vi) all comments received and responses; (vii) and all exhibits presented to the Board.

This "Supplement" document enumerates the significant changes made to the SUSMP that were directed by the Board at the hearing and the bases for the changes in the "Transcript of Proceedings", testimony presented or materials submitted to the Regional Board, and other relevant documents.

Applicability of the SUSMP

The SUSMP requirements apply to all projects in the nine enumerated categories for the Los Angeles County MS4 Program. While some development planning/ construction requirements in the permit are made applicable only to "Discretionary Projects", this limitation does not cover the seven "enumerated project categories" in Board Order No.

Definition of Parking Lots

The definition of "Parking Lots" has been reworded to eliminate the "stand alone" limitation, so that it now applies to all parking lots with 5,000 square feet or more or with 25 parking spaces or more and exposed to storm water.⁶

Definition of Redevelopment

The definition of "Redevelopment" has been reworded to include a minimum threshold of at least 5,000 square feet of impervious area addition to an existing property in order for the SUSMP requirements to apply. The threshold value is consistent with other threshold values in the SUSMP, such as Parking Lots and Restaurants.⁷

Definition of Restaurant

The definition of "Restaurant" has been reworded to limit applicability to "stand-alone" facilities and exclude co-located stalls or food counters in general purpose establishments such as markets and grocery stores.⁸

Definition of Retail Gasoline Outlet

The definition of "Retail Gasoline Outlet" has been reworded to include all retail gasoline outlets that sell gasoline and lubricating oils without consideration of the proportion of receipts derived from such sales.⁹

Conflict with Local Practices

The paragraph has been reworded to allow local ordinances to differ from the SUSMP so long as they are more stringent.¹⁰

Responsibility and Conditions for BMP Transfer

The language has been modified to ensure that the responsibility for the maintenance of Structural or Treatment Control BMPs is properly transferred with the sale of a property and is mandatory.¹¹

⁶ Ibid. at 301 and 306. Board Members Cloke and Diamond discuss and direct staff to eliminate the "stand-alone" limitation.

⁷ Ibid. at 67 and 302. Board Chairman Nahai discusses the absence of a minimum threshold and directs staff to set a minimum value to address his concerns of proportionality aberrations.

⁸ Ibid. at 68. Board Chairman interprets applicability and Dr. Swamikannu confirms the interpretation.

⁹ Ibid. at 46, 49, 308. Board Members discuss the staff proposed definition based on primary activity and direct staff to extend the definition to include all gas stations that pump gas.

¹⁰ Ibid. at 308. Board Members discuss the language and provide specific language for the purpose of local program consistency and to ensure adherence to the SUSMP requirements.

STANDARD URBAN STORM WATER MITIGATION PLAN
FOR LOS ANGELES COUNTY AND CITIES IN LOS ANGELES COUNTY

Final
Approved – Regional Board Executive Officer
March 8, 2000.

All projects that fall into one of seven categories are identified in the Los Angeles County MS4 Permit as requiring SUSMPs. These categories are:

- Single-Family Hillside Residences
- 100,000 Square Foot Commercial Developments
- Automotive Repair Shops
- Retail Gasoline Outlets
- Restaurants
- Home Subdivisions with 10 to 99 housing units
- Home Subdivisions with 100 or more housing units

The Regional Board Executive Officer has designated two additional categories subject to SUSMP requirements for the Los Angeles County MS4 Permit. These categories are:

- Location within or directly adjacent to or discharging directly to an environmentally sensitive area, and
- Parking lots 5,000 square feet or more or with 25 or more parking spaces and potentially exposed to storm water runoff

The City of Long Beach permit requires SUSMP for the following categories only: (i) 10-99 home subdivisions; (ii) 100 or more subdivisions; (iii) 100,000 or more square foot commercial developments; and (iv) Projects located adjacent to or discharging to environmentally sensitive areas. For the remaining five categories, equivalent requirements have been included directly in or are expected to be developed shortly under the City of Long Beach Storm Water Management Plan.

Permittees shall amend codes and promulgate ordinances not later than September 8, 2000, to give legal effect to the SUSMP requirements. The SUSMP requirements for projects identified herein shall take effect not later than October 8, 2000.

DEFINITIONS

“100,000 Square Foot Commercial Development” means any commercial development that creates at least 100,000 square feet of impermeable area, including parking areas. “Automotive Repair Shop” means a facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

“Best Management Practice (BMP)” means any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

“Commercial Development” means any development on private land that is not heavy industrial or residential. The category includes, but is not limited to: hospitals, laboratories and other medical facilities, educational institutions, recreational facilities, plant nurseries, multi-apartment buildings, car wash facilities, mini-malls and other business complexes, shopping malls, hotels, office buildings, public warehouses and other light industrial complexes.

"Restaurant" means a stand-alone facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812).

"Retail Gasoline Outlet" means any facility engaged in selling gasoline and lubricating oils.

"Source Control BMP" means any schedules of activities, prohibitions of practices, maintenance procedures, managerial practices or operational practices that aim to prevent storm water pollution by reducing the potential for contamination at the source of pollution.

"Storm Event" means a rainfall event that produces more than 0.1 inch of precipitation and that, which is separated from the previous storm event by at least 72 hours of dry weather.

"Structural BMP" means any structural facility designed and constructed to mitigate the adverse impacts of storm water and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both Treatment Control BMPs and Source Control BMPs.

"Treatment" means the application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

"Treatment Control BMP" means any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

CONFLICTS WITH LOCAL PRACTICES

Where provisions of the SUSMP requirements conflict with established local codes, (e.g., specific language of signage used on storm drain stenciling), the Permittee may continue the local practice and modify the SUSMP to be consistent with the code, except that to the extent that the standards in the SUSMP are more stringent than those under local codes, such more stringent standards shall apply.

SUSMP PROVISIONS APPLICABLE TO ALL CATEGORIES

The Maryland Stormwater Design Manual; Florida Development Manual: A Guide to Sound Land and Water Management; Denver Urban Storm Drainage Criteria Manual, Volume 3 – Best Management Practices and Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters, USEPA Report No. EPA-840-B-92-002, as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question. However, it is possible that a combination of BMPs not so designated, may in a particular circumstance, be better suited to maximize the reduction of the pollutants.

Examples of BMPs that can be used for minimizing the introduction of pollutants of concern generated from site runoff are identified in Table 2. Any BMP not specifically approved by the Regional Board in Resolution No. 99-03, "Approving Best Management Practices for Municipal Storm Water and Urban Runoff Programs in Los Angeles County", for development planning may be used if they have been recommended in one of the above references.

4. PROTECT SLOPES AND CHANNELS

Project plans must include BMPs consistent with local codes and ordinances and the SUSMP to decrease the potential of slopes and/or channels from eroding and impacting storm water runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Utilize natural drainage systems to the maximum extent practicable
- Control or reduce or eliminate flow to natural drainage systems to the maximum extent practicable
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion, with the approval of all agencies with jurisdiction, e.g., the U.S. Army Corps of Engineers and the California Department of Fish and Game

5. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the storm water conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins within the project area must be

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons why water quality controls will not function as designed or which may cause the system to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included or is required to include, Structural or Treatment Control BMPs in project plans, the Permittee shall require that the applicant provide verification of maintenance provisions through such means as may be appropriate, including, but not limited to legal agreements, covenants, CEQA mitigation requirements and/or Conditional Use Permits.

For all properties, the verification will include the developer's signed statement, as part of the project application, accepting responsibility for all structural and treatment control BMP maintenance until the time the property is transferred and, where applicable, a signed agreement from the public entity assuming responsibility for Structural or Treatment Control BMP maintenance. The transfer of property to a private or public owner must have conditions requiring the recipient to assume responsibility for maintenance of any Structural or Treatment Control BMP to be included in the sales or lease agreement for that property, and will be the owner's responsibility. The condition of transfer shall include a provision that the property owners conduct maintenance inspection of all Structural or Treatment Control BMPs at least once a year and retain proof of inspection. For residential properties where the Structural or Treatment Control BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&Rs). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what storm water management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. The transfer of this information shall also be required with any subsequent sale of the property.

If Structural or Treatment Control BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. Structural or Treatment Control BMPs proposed for transfer must meet design standards adopted by the public entity for the BMP installed and should be approved by the County or other appropriate public agency prior to its installation.

9. DESIGN STANDARDS FOR STRUCTURAL OR TREATMENT CONTROL BMPs

Structural or Treatment control BMPs selected for use at any project covered by this

A. 100,000 SQUARE FOOT COMMERCIAL DEVELOPMENTS

1. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water runoff or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

The activity of vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include in the project plans an area for washing/steam cleaning of vehicles and equipment. The area in the site design must be:

- Self-contained and/ or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

B. RESTAURANTS

1. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

The activity of outdoor equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include in the project plans an area for the

2. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact storm water if allowed to come into contact with storm water runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow storm water run-on or contact with storm water runoff.
- Design a repair/maintenance bay drainage system to capture all wash-water, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

3. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

The activity of vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the storm water conveyance system. Include in the project plans an area for washing/steam cleaning of vehicles and equipment. This area must be:

- Self-contained and/or covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer or to a permitted disposal facility.

4. PROPERLY DESIGN LOADING/UNLOADING DOCK AREAS

Loading/unloading dock areas have the potential for material spills to be quickly transported to the storm water conveyance system. To minimize this potential, the following design criteria are required:

- Cover loading dock areas or design drainage to minimize run-on and runoff of storm water.
- Direct connections to storm drains from depressed loading docks (truck wells) are prohibited.

E. PARKING LOTS

1. PROPERLY DESIGN PARKING AREA

Parking lots contain pollutants such as heavy metals, oil and grease, and polycyclic aromatic hydrocarbons that are deposited on parking lot surfaces by motor-vehicles. These pollutants are directly transported to surface waters. To minimize the offsite transport of pollutants, the following design criteria are required:

12. LIMITATION ON USE OF INFILTRATION BMPs

Three factors significantly influence the potential for storm water to contaminate ground water. They are (i) pollutant mobility, (ii) pollutant abundance in storm water, (iii) and soluble fraction of pollutant. The risk of contamination of groundwater may be reduced by pretreatment of storm water. A discussion of limitations and guidance for infiltration practices is contained in, *Potential Groundwater Contamination from Intentional and Non-Intentional Stormwater Infiltration, Report No. EPA/600/IR-94/051, USEPA (1994)*.

In addition, the distance of the groundwater table from the infiltration BMP may also be a factor determining the risk of contamination. A water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic.

Infiltration BMPs are not recommended for areas of industrial activity or areas subject to high vehicular traffic (25,000 or greater average daily traffic (ADT) on main roadway or 15,000 or more ADT on any intersecting roadway) unless appropriate pretreatment is provided to ensure groundwater is protected and the infiltration BMP is not rendered ineffective by overload.

13. ALTERNATIVE CERTIFICATION FOR STORM WATER TREATMENT MITIGATION

In lieu of conducting detailed BMP review to verify Structural or Treatment Control BMPs adequacy, a Permittee may elect to accept a signed certification from a Civil Engineer or a Licensed Architect registered in the State of California, that the plan meets the criteria established herein. The Permittee is encouraged to verify that certifying person(s) have been trained on BMP design for water quality, not more than two years prior to the signature date. Training conducted by an organization with storm water BMP design expertise (e.g., a University, American Society of Civil Engineers, American Society of Landscape Architects, American Public Works Association, or the California Water Environment Association) may be considered qualifying.

TABLE 2

EXAMPLE BEST MANAGEMENT PRACTICES (BMPs)

The following are examples of BMPs that can be used for minimizing the introduction of pollutants of concern that may result in significant impacts, generated from site runoff to the storm water conveyance system. (See Table 1: Suggested Resources for additional sources of information):

- Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths must still comply with regulations for the Americans with Disabilities Act and other life safety requirements.
- Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.
- Comply with all zoning and applicable ordinances to minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.
- Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).
- Use open space development that incorporates smaller lot sizes.
- Reduce building density.
- Comply with all zoning and applicable ordinances to reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.
- Comply with all zoning and applicable ordinances to reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.
- Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas, and avoid routing rooftop runoff to the roadway or the storm water conveyance system.
- Vegetated swales and strips
- Extended/dry detention basins
- Infiltration basin
- Infiltration trenches
- Wet ponds
- Constructed wetlands
- Oil/Water separators
- Catch basin inserts
- Continuous flow deflection/ separation systems
- Storm drain inserts
- Media filtration
- Bioretention facility
- Dry-wells
- Cisterns
- Foundation planting
- Catch basin screens
- Normal flow storage/ separation systems
- Clarifiers
- Filtration systems
- Primary waste water treatment systems

WMI OVERVIEW

A. Goals and objectives

A key goal of the State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (RWQCBs) is to provide water resource protection, enhancement, and restoration while balancing economic and environmental impacts. This is done using an integrated planning approach called the Watershed Management Initiative (WMI). The main ideas that define the WMI and distinguish it from previous efforts are as follows:

1. Water resource problems are identified and prioritized primarily on the basis of water quality within individual watersheds (geographic drainage areas used for management purposes). Unique solutions are developed for each watershed that consider all local conditions and pollution sources and rely on the input and involvement of local stakeholders.
2. Historically, the SWRCB's programs have functioned on a statewide and/or region-wide basis. This has worked reasonably well for controlling conventional pollutants from point sources, but has not proven adequate to address nonpoint sources of pollution. The WMI will better coordinate existing efforts to regulate point source problems along with efforts to address challenges from the threat of nonpoint source pollution. This involves establishing working relationships between staff who previously worked only within a single program.
3. The RWQCBs work collaboratively with local stakeholder groups. In conjunction with the SWRCB, they attempt to coordinate the actions of governmental agencies and programs to best assist the local groups. Better coordination of the many overlapping state and federal activities, especially those involving regulations and funding, is critical to the success of local watershed groups.

B. Framework for implementation

The SWRCB and RWQCBs, in partnership with the U.S. Environmental Protection Agency (USEPA), have developed an integrated planning process to more effectively and efficiently direct the limited State and federal funds to the highest priority activities. Statewide priorities are developed collaboratively by the SWRCB, USEPA and the RWQCBs. These priorities and the planning process are described in the WMI Integrated Plan.

Process for Development of the Final California Unified Watershed Assessment

(in response to the federal Clean Water Action Plan, October 1, 1998)

Introduction

The Clean Water Action Plan, released by President William Clinton and Vice-President Albert Gore on February 19, 1998, requested that States and Tribes, with assistance from federal agencies and input from stakeholders and the public, convene a collaborative process to develop a Unified Watershed Assessment (UWA) to guide allocation of new federal resources for watershed protection. The Plan calls for watersheds to be placed into one of four categories:

- Category I - Watersheds that are candidates for increased restoration activities due to impaired water quality or other impaired natural resource goals (emphasis on aquatic systems).
- Category II - Watersheds with good water quality that, through regular program activities, can be sustained and improved.
- Category III - Watersheds with pristine or sensitive areas on federal, state or tribal lands that need protection.
- Category IV - Watersheds where more information is needed in order to categorize them.

The Plan also calls for states and tribes, in collaboration with others, to establish priorities among Category I watersheds for the purpose of targeting proposed new federal funds during the 1999 and 2000 federal fiscal years. A deadline of August 1 was established to complete a draft Assessment and list of Priority Watersheds to be sent out for public review. The Plan established a deadline of October 1 to issue a final Assessment and Prioritization. The October 1 deadline coincides with the beginning of the federal fiscal year and the potential availability of new funds for restoring watersheds. Not all the priority watersheds identified in the Unified Watershed Assessment (UWA) will necessarily receive funding under the Clean Water Action Plan and the extent to which Congress will provide funding, if any, is unknown at this time.

The Plan also calls for specific activities to be completed after October 1, including identifying restoration action strategies for the priority Category I watersheds and developing a long term schedule for addressing the nonpriority Category I watersheds.

Description of the California Process

In California, the process for developing the UWA was convened jointly by State Water Resources Control Board staff and the United States Department of Agriculture Natural Resources Conservation Service, in collaboration with Tribes, other state and federal natural resource agencies, local governments, universities, and a variety of stakeholder groups. The over 100 Tribal Nations located within California were given the option of collaborating with the state process, or convening a

UWA, and to develop the public process for commenting on the draft assessment. The University of California at Davis, Information Center for the Environment, played a key role in assembling, analyzing and processing the various databases and assessments in Geographic Information Systems (GIS) format to compile the UWA using the criteria set by the working group.

A Draft California Unified Watershed Assessment was released for public review through a mail-out to over 2,100 stakeholders and posting on the California NRCS Website on August 1, 1998. A copy of the Draft California UWA was also submitted to the National UWA Workgroup on August 1, 1998. Written comments on the product were due to the State Water Resources Control Board by August 31, 1998.

Over 170 written comments were received on the Draft Assessment. These were reviewed at a September 8 meeting of the State Technical Committee, with Committee members being asked for their recommendations on how to process and incorporate the comments. The California working group met on September 14 and 18 to incorporate the State Technical Committee recommendations and public comments into a final assessment for California. The working group was expanded at these meetings to include greater representation from local governments, watershed groups and state agencies, namely, the Regional Council of Rural Counties, Nevada County Resource Conservation District, Yuba River Watershed Group, and Caltrans.

There has been much interest in California in the development of the Unified Watershed Assessment, including interest in the process, the product itself, and the ways in which the product will be used, now and in the future. From the beginning of the process, and continuing in the written comments, there was great concern over the short time frame given to produce the assessment product. To address this concern, the UWA is being viewed in California as a dynamic ongoing process, with the October 1, 1998, version of the product being used to target federal fiscal year 1999 and 2000 funds only. The assessment will continue to be reviewed and improved by the working group, with greater local government and stakeholder involvement, before future funding decisions are made.

Watershed Boundaries

The watershed boundaries being used in the assessment are the federal 8-digit cataloging unit boundaries, also known as federal hydrologic units, established by the U.S. Geologic Survey. These boundaries were obtained from the CALWATER 2.0 database, currently available from Teale Data Center and the California Department of Fish and Game. A modification of the 8-digit boundary was made in one watershed, the Tulare-Buena Vista Lakes Basin, located in Central California, and it was broken into three separate watersheds, using the state hydrologic subarea boundaries for the division. Using these boundaries, a total of 149 watersheds fall completely or partially in California. A crosswalk exists that matches the federal 8-digit cataloging unit with the state hydrologic subarea boundaries.

substantially met. Category II watersheds were defined by first placing watersheds in Category I, according to the criteria outlined above. Second, the criteria for Category III watersheds were applied to the remaining watersheds and classified, as appropriate. Third, it was decided that all remaining watersheds (if any were left unclassified) would be placed in Category II, by default. These would then be examined individually by the working group to be sure Category II was the appropriate classification for them.

Criteria for Category III Watersheds:

Category III watersheds are those that have significant areas of government-owned lands (federal, state and tribal lands) that contain pristine or sensitive areas that need protection. Watersheds are considered to be Category III, if they are not impaired (i.e. not Category I), and a significant portion (more than 25 percent) of the watershed consists of:

Criteria for Pristine or Sensitive Areas

-Designated wilderness areas, National Park Service Lands, BLM Areas of Critical Environmental Concern, National Recreation Areas, State Parks & Reserves

-Federal and State Wild and Scenic Rivers (DF&G)

Database/Assessment Used

Managed Areas Data Layer of U.S. Geologic Survey GAP Analysis Program (Level 1 Management Areas)

Federal and State Wild and Scenic Rivers data layer)

Criteria for Category IV Watersheds and Information Needs:

The initial Unified Watershed Assessment attempted to determine whether there were important environmental restoration needs in each individual watershed. At the scale of major watersheds (Hydrologic Units) treated in the California UWA, there is sufficient information in virtually every watershed to show whether any major waterways are impaired. Therefore, the California UWA does not identify any Category IV watersheds (insufficient information available). It is important to note, however, that this is not meant to imply that we do not need any more information about the condition of California watersheds. Even if there is enough information to document pressing restoration needs in many watersheds, assessment data for any given watershed are often incomplete and fragmentary. Resources are needed to develop better assessment data and information systems.

The working group, which represented a broad cross-section of agencies and stakeholders with an interest in water quality and land use policy, achieved a surprising level of consensus in setting priorities for watershed restoration. This success may be due in large part to the availability of pre-existing synthetic data sources and assessment tools for evaluating water-related resources. A variety of regional efforts, including the Sierra Nevada Ecosystem Project, the Interagency Ecological Program for the Bay-Delta Ecosystem, and Natural Community Conservation Planning efforts in Southern California, have developed integrated data and bioregional assessments for major portions of the California landscape. More recently, the California Biodiversity Council (which includes the heads of most of the state and federal resource management agencies in California) has sponsored a variety of efforts to coordinate data and provide better information to local policymakers. Data libraries and assessment tools from two Biodiversity Council initiatives, the California Rivers Assessment and the Natural Resources Project Inventory, provided an assessment framework for the UWA, augmented by data contributions from a number of other participants.

Criteria for Priority Watersheds

High Value

- Presence of Tribal Lands (from BIA Database)
- % Native Fish Species Richness (from Dr. Peter Moyle, UCD)
- Numbers of rare, aquatic, riparian and wetlands species present (DF&G Natural Diversity Database)
- Wetland & Vernal Pools Ranking (DF&G, Coastal Conservancy, EPA, NRCS, UCD-ICE professional judgment)
- Presence of anadromous salmonid fish species (NMFS Anadromous Species Status Review)
- Percentage of watershed with protected areas (USGS GAP Analysis Program - Level 1 Mgt. Areas)
- Percentage of watershed in native vegetation (USGS GAP Analysis Program - Vegetation Data Layer)
- State and Federal Wild and Scenic Rivers (DF&G data layer)
- Aquatic Diversity Management Areas (Dr. Peter Moyle, UCD)
- Watersheds identified as having impairments for beneficial uses (SWRCB 303(d) list)
- Population Density (CA Dept. of Finance)
- Presence of proposed and listed threatened and endangered aquatic, wetland, anadromous salmonid and total species (DF&G Natural Diversity Database & NMFS Anadromous Species Status Review)
- High susceptibility for sediment production due to very high fuels hazard (CDF Wildfire Potential database); landslides (USFS Analysis of CDF state roads data and State Geologic Map of CA, Jennings, 1977); or surface erosion (USFS Analysis of STATSGO soils data)
- SWRCB and RWQCB impaired and priority watersheds from 303(d) list and Watershed Management Initiative
- USDA Geographic Priority Areas identified by Local Working Groups (from USDA Environmental Quality Incentives Program)
- Number of watershed projects (from Natural Resource Projects Inventory database, excluding the noxious weeds database, UCD-ICE)
- Presence of Tribes with clean water programs (i.e. those Tribes with the "Treated as A State," or TAS designation from EPA)

High Risk

High Opportunity

Specific Geographic Information Systems (GIS) databases were used to apply these criteria to each of the watersheds. Watersheds were assigned numerical rankings for the state of the watershed with respect to each criterion. The rankings for the individual criteria for each watershed were then added together to create a total point count for each watershed within each area of importance - i.e. for high value, high risk and high opportunity.

The final California Unified Watershed Assessment identifies 66 priority Category I watersheds. The final list of priority watersheds was developed using a combination of the criteria/data analysis; public comments; and current watershed priorities of the State Water Resources Control Board. The data analysis yielded 34 priority watersheds by selecting those watersheds that ranked out to be above average (top 50 percent) in all three areas of high value, high risk and high opportunity, combined. The working group weighted the criteria used equally (in other words, each of the elements listed above contributed more or less equally to the draft recommendations.) The public comments yielded

NOISE TECHNICAL REPORT

NOISE IMPACT ANALYSIS

CHATSWORTH RIDGE ESTATES PROJECT

CHATSWORTH, CALIFORNIA

Prepared for:

**HDR/Urban Vision
Attn: Deanna Hansen
707 Wilshire Blvd., Ste. 5320
Los Angeles, CA 90017**

Date:

November 14, 2001

NOISE SETTING

Sound is mechanical energy transmitted by pressure waves in a compressible medium such as air. Noise is commonly defined as unwanted sound. Sound is characterized by various parameters that describe the rate of oscillation of sound waves, the distance between successive troughs or crests, the speed of propagation, and the pressure level or energy content of a given sound wave. In particular, the sound pressure level has become the most common descriptor used to characterize the loudness of an ambient sound level. The unit of sound pressure ratioed to the level barely detectable by a young person with good auditory acuity is called a decibel (dB). Because sound or noise can vary in intensity by over one million times within the range of human hearing, a logarithmic loudness scale similar to the Richter Scale used in earthquake magnitude is used to keep sound intensity numbers at a convenient and manageable level. Since the human ear is not equally sensitive to all sound frequencies within the entire spectrum, noise levels at maximum human sensitivity are factored more heavily into sound descriptions in a process called "A-weighting" written as dB(A). Any further reference to decibels written as "dB" should be understood to be A-weighted.

Time variations in noise exposure are typically expressed in terms of a steady-state energy level equal to the energy content of the time varying period (called Leq), or, alternately, as a statistical description of the sound level that is exceeded over some fraction of a given observation period. Finally, because community receptors are more sensitive to unwanted noise intrusion during the evening and at night, State law requires that, for planning purposes, an artificial dB increment be added to quiet time noise levels in a 24-hour noise descriptor called the Community Noise Equivalent Level (CNEL).

An interior CNEL of 45 dB(A) is mandated by multiple family dwellings in Title 24 of the California Code of Regulations. In 1988, the State Building Standards Commission recommended that the 45 dB CNEL interior standard be expanded to include all habitable rooms for all residential occupancy, including single family. The Los Angeles County has required a 45 dB CNEL interior standard for all occupancies well before the adoption of the statewide guidelines. Since typical noise attenuation within residential structures with closed windows is about 20 dB, an exterior noise exposure of 65 dB CNEL is generally the noise/land use compatibility guideline for new residential dwellings in California. A 65 dB CNEL exterior level is also the noise threshold where noise begins to substantially interfere with enjoyment of any outdoor recreational amenity such as a yard, patio, spa/pool, etc. Mitigation of exterior noise to at least 65

function of the equipment used and short-term variations are strongly influenced by topographical factors that may somewhat change during the course of the project. Construction noise tends to occur in discrete phases dominated initially by earth-moving sources and later for finish construction. The heavy equipment noise typically ranges up to about 90 dB(A) at 50 feet from the source. Figure 1 summarizes the noise generation for typical construction activities.

Point sources of noise emissions are atmospherically attenuated by a factor of 6 dB per doubling of distance. The loudest construction will require more than 1000 feet of distance between the source and a nearby receiver to reduce the 90 dB(A) source strength to a generally acceptable 65 dB exterior exposure level. However, the complicated terrain of the project site will shield nearby receivers from direct line of sight noise propagation such that the construction equipment noise "envelope" will be smaller than 1000 feet. Construction noise may, at times, be audible at the existing residences near the project site. Such events will be intermittent depending upon the intervening terrain. The number of potentially impacted receivers and the duration of clear audibility of construction equipment activity noise will be small.

Construction noise sources are not strictly relatable to a 24-hour community noise standard because they occur only during selected times and the source strength varies sharply with time. Construction activities are also treated separately in various community noise ordinances because they do not represent a chronic, permanent noise source. To abate the potential nuisance from construction noise, especially in very close proximity to any nearby noise-sensitive development, the Los Angeles County Noise Ordinance (Section 12.08.440 of the County Code) limits the hours of allowable construction activities and establishes noise performance standards at the nearest residential structures.

Section 12.08.440(A) limits the allowable hours of construction activities to 7 a.m. to 7 p.m. on Monday through Saturday except in an emergency. The noise performance standards in Section 12.08.440(B) of the Code distinguish between short-term (less than ten days) and long-term activities with the following standards:

Short-Term Activity:

	<u>Single Family</u>	<u>Multi- Family</u>	<u>Semi- Residential</u>
Daily, 7 a.m. - 8 p.m.	75	80	85
8 p.m. - 7 a.m. + Sunday & Holiday	60	65	70

Long-Term Activity:

Daily, 7 a.m. - 8 p.m.	60	65	70
8 p.m. - 7 a.m. + Sunday & Holiday	50	55	60

These noise values are indicated to be maxima. Because of their stringency for long-term operations, they could possibly be exceeded within close proximity to adjacent development for brief periods. If, however, they were exceeded with any considerable magnitude, either in terms of number of events or degree of excess noise, the County has the authority to shut the construction activity down. Because of the transitory nature of most construction activity noise impacts, the enforcement authority relative to the noise performance standards in Section 12.08.440(B) have been rarely invoked.

Enforcement of the ordinance thus provides a reasonable measure of protection for nearby residents in those localized instances where major earthworks occur within close proximity to existing residences. With a combination of an adequate distance buffer for most major earthworks, terrain shielding for many receivers and compliance with County ordinances, site development will not create a significant noise impact on the adjacent community.

Traffic Noise Impacts

The proposed development will generate around 4,422 vehicle trips per day (Linscott, Law & Greenspan, 2001). Traffic noise changes on areawide roadways were calculated using the FHWA Highway Traffic Noise Model (FHWA-RD-77-108) initialized with traffic input parameters (i.e., traffic volumes) supplied by the EIR traffic consultant. The impact analysis was conducted in areas of

MITIGATION

Temporary construction noise may be occasionally audible at scattered homes within/around the project site. Such impacts will be highly localized as there is generally both adequate distance and terrain shielding to minimize residential exposure to site construction activity noise. Construction noise impacts will be further minimized by compliance with County Noise Ordinance Section 12.08.440 limiting allowable hours of construction activities and prohibiting the creation of any excessively loud, unnecessary or unusual equipment noise.

No significant off-site noise impacts deriving from project-related traffic were identified requiring impact mitigation.

Potential on-site noise impacts are confined to the development perimeter in closest proximity to SR-118. Exterior levels at usable space such as patios are predicted to slightly exceed the Los Angeles County exterior noise standard of 65 dB CNEL. The following mitigation measures are required to meet all noise exposure guidelines:

- (1) A solid masonry (or similarly effective barrier) is required at the top of the rear yard slope along the southern lot perimeter of Lots 1-11 and Lots 45-55.
- (2) Freeway-facing, second-story windows along the southernmost tier of development will require acoustical upgrades such as thicker glass or dual-paned glazing.
- (3) Central air conditioning should be a standard feature in all southern project-perimeter homes.

APPENDIX M

TRAFFIC STUDY

MEMORANDUM

DATE: October 24, 2001

TO: Hans Giraud, Hans Giraud & Associates

FROM: David Shender, LLG Engineers

REFERENCE: 1-982714-2

SUBJECT: Chatsworth Ridge Estates Project
Updated tables/exhibits based on 484 dwelling units

As requested, we have prepared the following updated analysis associated with the proposed Chatsworth Ridge Estates Project. As you know, our office prepared a traffic impact study (dated March 22, 2001) which examined the potential project related traffic impacts in association with development of 538 dwelling units. The following paragraphs provide the updated analyses for this project which reflects a reduction from 538 dwellings units to 484 dwelling units.

Project Trip Generation

Table 2 attached summarizes the traffic generation forecast for the 484-dwelling unit project. As shown, the proposed project is expected to generate 348 vehicle trips (87 inbound and 261 outbound) and 445 vehicle trips (285 inbound and 160 outbound) during the weekday AM and PM peak hours, respectively. Over a 24-hour period, the project is forecasted to generate 4,422 daily trip ends during a typical weekday (2,211 inbound and 2,211 outbound trips).

The attached Exhibits 7 and 8 display the updated project traffic volumes for the AM and PM peak hours, respectively.

Traffic Impact Analysis: Future With Project Condition

The attached Exhibits 14 and 15 display the future with project traffic volumes at the study intersections for the AM and PM peak hours, respectively. Summaries of the updated V/C ratios and LOS values are shown in Tables 5 and 6. The LOS worksheets for the study intersections are also attached.

In summary, due to the reduced number of dwelling units, the V/C ratios for the "With Project" conditions as well as the incremental impacts due to the project are slightly less than those stated in the March 22, 2001 traffic impact study. However, the number of study intersections with significant impacts during the AM and PM peak hours remains unchanged at three. With the previously recommended mitigation measures at the impacted locations, the project impacts at the three study intersections are expected to be fully mitigated.

- * Key conflicting movement as a part of ICU
- 1 Counts conducted by Accutek
- 2 Capacity expressed in veh/hour of green
- 3 Southbound movement considers the westbound movement and volumes from Mayan Drive.
- 4 Eastbound movement considers the eastbound movement and volumes from Poema Place.
- 5 Project mitigation measures include: (i) widening of the westbound SR-118 off-ramp to provide one left-turn lane, one through/left-turn lane, and one right-turn only lane; (ii) widening of Mayan Drive to provide one left-turn lane and one through/right-turn lane; and (iii) widening of Poema Place to provide one through/right-turn lane and one right-turn only lane.

EXECUTIVE SUMMARY

The purpose of this study is to evaluate the traffic impacts associated with the development of 538 single-family residential units, to be located north of the State Route 118 Freeway between Topanga Canyon Boulevard and De Soto Avenue in the unincorporated area of Los Angeles County. The project is expected to generate 387 vehicle trips during the AM peak hour and 489 vehicle trips during the PM peak hour. Over a 24-hour period the proposed project is forecasted to generate 4,874 daily trip ends during a typical weekday.

While the project site is in an unincorporated area of Los Angeles County, the street system that provides access to the site is primarily located within the City of Los Angeles. In order to evaluate the potential impacts to the local street system, the City of Los Angeles Department of Transportation (LADOT) staff determined that 13 intersections (two of which are located in County of Los Angeles' jurisdiction) were required for analysis to determine changes in operations following occupancy and utilization of the project. The Intersection Capacity Utilization (ICU) method (County of Los Angeles intersections) and the Critical Movement Analysis (CMA) method (City of Los Angeles intersections) were utilized to determine Volume-to-Capacity ratios and corresponding Levels of Service. The study intersections analyzed are as follows:

1. Topanga Canyon Boulevard & Poema Place/Mayan Drive (County)
2. Topanga Canyon Boulevard & SR-118 WB On/Off Ramps (County)
3. Topanga Canyon Boulevard & SR-118 EB On/Off Ramps
4. Topanga Canyon Boulevard & Santa Susana Pass Road
5. Topanga Canyon Boulevard & Chatsworth Street
6. Topanga Canyon Boulevard & Devonshire Street
7. Canoga Avenue & Rinaldi Street
8. Canoga Avenue & Chatsworth Street
9. Canoga Avenue & Devonshire Street
10. De Soto Avenue & SR-118 WB On/Off Ramps
11. De Soto Avenue & SR-118 EB On/Off Ramps
12. De Soto Avenue & Chatsworth Street
13. De Soto Avenue & Devonshire Street

De Soto Avenue & Chatsworth Street

- Fund the implementation of the City of Los Angeles ATSAC system at this intersection.

To summarize, the recommended traffic mitigation measures at the Topanga Canyon Boulevard terminus area provide significant improvements to traffic flow based on the following:

- The incorporation of the Poema Place and Mayan Drive/A Street approaches within the overall traffic signal control of the intersection substantially improves the efficiency (and safety) of traffic movements to and from these streets.
- The additional capacity provided at the intersection (i.e., expanding the Poema Place approach from one to two lanes, expanding the Mayan Drive/A Street approach from one to two lanes, and providing a new right-turn only lane on the SR 118 westbound off-ramp) allows for more vehicles to travel through the intersection during a green light phase, thus reducing the queues and delays currently experienced by motorists.

Incremental, but not significant impacts are forecasted at the remaining ten study intersections. Furthermore, the traffic analysis also determined that Canoga Avenue would continue to operate at very good levels of service, even after the addition of traffic generated by the proposed project (e.g., all three study intersections on Canoga Avenue are projected to continue operate at LOS A during the AM peak hour and LOS A or LOS B during the PM peak hour).

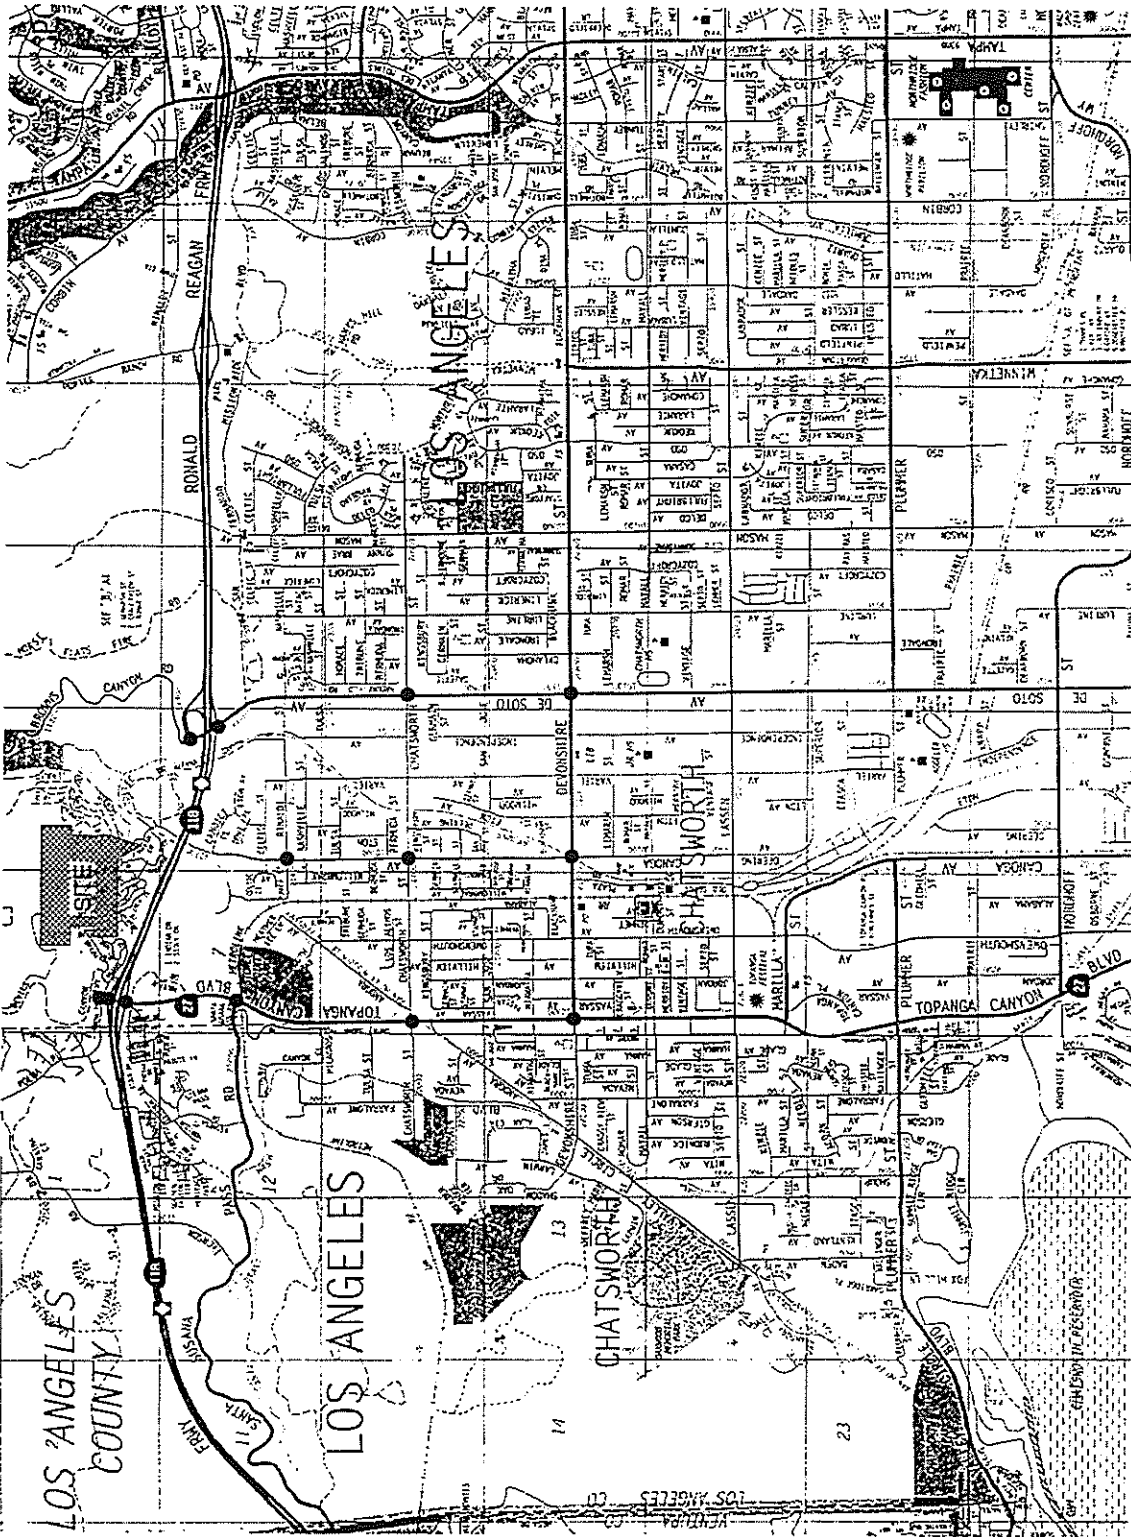

Other key items discussed in the report include a Congestion Management Program (CMP) roadway impact analysis and a transit impact analysis. The Topanga Canyon Boulevard and SR-118 Freeway Westbound On/OffRamps intersection is a CMP monitoring location. Based on the CMP significant impact criteria, a project-related impact is anticipated at this intersection. The roadway improvement measure for this intersection, as described above, is expected to improve overall operations of this intersection, thereby reducing the project impacts to less than significant levels. No other CMP monitoring locations would be significantly impacted by the proposed project.

**TRAFFIC IMPACT STUDY
CHATSWORTH RIDGE ESTATES PROJECT
CHATSWORTH, CALIFORNIA**

INTRODUCTION

This traffic analysis has been conducted to identify and evaluate the potential impacts that traffic generated by the development of the proposed Chatsworth Ridge Estates Residential Project will have on the local roadway network. The proposed project is located north of the State Route 118 Freeway between Topanga Canyon Boulevard and De Soto Avenue in the unincorporated area of Los Angeles County. The development will provide a total of 538 residential units.

The traffic analysis follows County of Los Angeles and City of Los Angeles traffic study guidelines and evaluates potential project-related impacts associated with the proposed development at 13 key intersections in the vicinity of the project site. The study intersections were determined by City of Los Angeles Department of Transportation (LADOT) staff, and confirmed with staff from the Los Angeles County Department of Public Works (LACDPW), Traffic and Lighting Division. While the project site is in an unincorporated area of Los Angeles County, 11 of the 13 study intersections are located within the City of Los Angeles. The Critical Movement Analysis (CMA) method was used to determine Volume-to-Capacity (V/C) ratios and Levels of Service (LOS) at the 11 City of Los Angeles study intersections while the Intersection Capacity Utilization (ICU) method was used to determine the V/C and LOS at the two County of Los Angeles study intersections.

VICINITY MAP

Nine of the 13 study intersections selected for analysis are controlled by traffic signals. The existing lane configurations at the 13 study intersections are displayed in Exhibit 3. A brief description of the important roadways in the project vicinity is provided in the following paragraphs.

The Ronald Reagan Freeway (State Route 118) extends from the Foothill Freeway (Route 210) to Ventura County. The freeway serves Simi Valley as well as the northern portions of the San Fernando Valley. In the project vicinity, the Ronald Reagan Freeway generally consists of four mainline travel lanes plus a high occupancy vehicle (HOV) lane in each direction. On/Off Ramps were analyzed at both Topanga Canyon Boulevard and De Soto Avenue as part of this study. It should be noted that the freeway ramps located at De Soto Avenue are presently not signalized.

Topanga Canyon Boulevard is a state highway (SR 27) and a major north-south route across the San Fernando Valley which terminates just north of the SR 118 Freeway. Two travel lanes are provided on Topanga Canyon Boulevard in each direction. Near Devonshire Street, three southbound travel lanes are provided. The posted speed limits on Topanga Canyon Boulevard vary between 40 and 45 miles per hour (MPH). Tow Away No Stopping Anytime (TANSAT) signs are posted on both sides of Topanga Canyon Boulevard in the project vicinity. Near Santa Susana Pass Road, parking is generally permitted on both sides of Topanga Canyon Boulevard between 6:00 AM and 10:00 PM. South of Chatsworth Street, no parking is permitted on the west side of Topanga Canyon Boulevard.

Canoga Avenue is a north-south roadway in the project vicinity. One through travel lane is generally provided in each direction. Near Devonshire Street, two travel lanes are provided in each direction. Canoga Avenue is posted for a 35 MPH speed limit. North of Rinaldi Street, parking is prohibited on both sides of Canoga Avenue. South of Rinaldi Street, parking is permitted in some areas.

De Soto Avenue is a north-south roadway which terminates just north of the SR 118 Freeway. Two travel lanes are provided in each direction north of Chatsworth Street and three travel lanes are provided in each direction south of Chatsworth Street. The posted speed limits on De Soto Avenue vary between 40 MPH and 45 MPH. In the project vicinity, no parking on De Soto Avenue is permitted.

Poema Place/Mayan Drive is an east-west roadway that connects with Topanga Canyon Boulevard and forms a “Tee” intersection. Poema Place comprises the west leg of the intersection and Mayan Drive (a private road) comprises the east leg of the intersection. The posted speed limit on Poema Place is 35 MPH and parking is generally permitted. It should be noted that Mayan Drive, which is currently unimproved (i.e., no curb and gutter), will provide immediate access to the proposed project site.

Santa Susana Pass Road is an east-west roadway located south of the proposed project and terminates at Topanga Canyon Boulevard. One through travel lane is provided in each direction. The posted speed limit on Santa Susana Pass Road is 35 MPH. Bike lanes are provided while parking is not permitted on Santa Susana Pass Road.

Rinaldi Street is a residential east-west roadway south of the project area. Rinaldi Street provides one through travel lane in each direction. Parking is generally permitted on Rinaldi Street east of Canoga Avenue. West of Canoga Avenue, Rinaldi Street is signed as “Not a Through Street”.

Chatsworth Street is an east-west roadway located south of the project area. One travel lane is generally provided in each direction. Parking is permitted in some area on Chatsworth Street. The posted speed limit on Chatsworth Street is 35 MPH.

MTA Line 167

MTA Line 167 provides service along De Soto Street, Devonshire Street, and Lassen Street in the project vicinity, including service to the Chatsworth Transportation Center. In the AM peak hour, Line 167 provides headways of three buses in the westbound/northbound direction and three buses in the eastbound/southbound direction. During the PM peak hour, Line 167 provides headways of two buses in each direction.

MTA Line 168

MTA Line 168 provides service along Topanga Canyon Boulevard and Lassen Street in the project vicinity, including service to the Chatsworth Transportation Center. During the AM peak hour, Line 168 provides headways of one bus in the eastbound and one bus in the westbound direction. During the PM peak hour, Line 168 provides headways of one bus per hour in each direction.

MTA Line 243

MTA Line 243 provides service along Canoga Avenue, De Soto Avenue, Mason Avenue, Devonshire Street, and Lassen Street in the project vicinity, including service to the Chatsworth Transportation Center. During the AM peak hour in the project vicinity, Line 243 provides headways of five buses in the northbound direction and four buses in the southbound direction. During the PM peak hour, Line 243 provides headways of two buses per hour in each direction.

MTA Line 245

MTA Line 245 provides service along Topanga Canyon Boulevard, Canoga Avenue, Devonshire Street, and Lassen Street in the project vicinity, including service to the Chatsworth Transportation Center. During the AM peak hour, Line 245 provides headways of two buses in the northbound direction and two buses in the southbound direction. During the PM peak hour, Line 245 provides headways of one bus in each direction.

West Valley Smart Shuttle

The West Valley Smart Shuttle provides both demand-response and fixed-route service in the project vicinity. The Smart Shuttle provides headways every thirty minutes at several access points in the project study area, including the Chatsworth Transportation Center, the Chatsworth High School, Lawrence Middle School, and Mason Recreation Center & Park.

Metrolink Commuter Rail

Metrolink is a regional commuter train system which provides service within the Los Angeles, Ventura, Orange, Riverside, and San Bernardino counties. The Chatsworth Metrolink station is located approximately one-half block south of Devonshire Boulevard between Canoga Avenue and Owensmouth Avenue at the Chatsworth Transportation Center. The Chatsworth Metrolink station connects with several bus transit operators including six MTA lines, the LADOT Commuter Express Line 419, SCT Line 791, the Simi Valley Transit Route C, and the West Valley Smart Shuttle.

TRAFFIC COUNTS

Manual counts of vehicular turning movements were conducted at each of the thirteen study intersections during the morning (AM) and afternoon (PM) commuter periods to determine the peak hour traffic volumes. Traffic volumes at the study intersections show the typical peak periods between 7:00 AM to 10:00 AM and between 3:00 PM to 6:00 PM which are generally associated with weekday peak commuter hours. Table 1 summarizes the AM and PM peak hour manual counts at the study intersections. The existing traffic volumes at the study intersections during the AM and PM peak hours are shown in Exhibits 4 and 5, respectively. Summary sheets of the manual counts are contained in Appendix A.

PROJECT TRAFFIC VOLUMES

AM PEAK HOUR

CHATSWORTH RIDGE ESTATES

projects research was conducted based on information on file at the City of Los Angeles Department of Planning and the City of Los Angeles Department of Transportation. The list of other known development projects in the area is presented in Table 3. Exhibit 9 shows the location of the related projects.

Traffic volumes expected to be generated by the related projects were calculated using rates provided in the ITE *Trip Generation* manual, or were obtained from previously approved traffic impact studies. Table 4 shows the related projects respective traffic generation for the AM and PM peak hours, as well as on a daily basis for a typical weekday. Exhibits 10 and 11 display the anticipated distribution of the related projects traffic volumes to the study intersections during the AM and PM peak hours, respectively.

In order to account for unknown related projects not included in this analysis, the existing traffic volumes were increased at an annual rate of two percent (2%) to the year 2005 (i.e., the anticipated year of project build-out). Application of this "ambient growth" factor allows for a conservative "worst case" forecast of future traffic volumes in the area.

TRAFFIC IMPACT ANALYSIS METHODOLOGY

The County of Los Angeles study intersections were evaluated using the Intersection Capacity Utilization (ICU) method of analysis, and the City of Los Angeles study intersections were evaluated using the Critical Movement Analysis (CMA) method of analysis. Both methods determine Volume-to-Capacity (V/C) ratio on a critical lane basis. The overall intersection V/C ratio is subsequently assigned a Level of Service (LOS) value to describe intersection operations. The LOS vary from LOS A (free flow) to LOS F (jammed condition). It should be noted that LOS D is typically recognized as the minimum acceptable level of service in urban areas. Appendix B provides descriptions of both the ICU and CMA methods and their corresponding Levels of Service.

RELATED PROJECTS TRAFFIC VOLUMES
AM PEAK HOUR
CHATSWORTH RIDGE ESTATES

Impact Criteria and Thresholds

The relative impact of the added project traffic volumes expected to be generated by the proposed Chatsworth Ridge Estates project during the AM and PM peak hours was evaluated based on analysis of future operating conditions at the thirteen study intersections, without and with the proposed project. The previously discussed capacity analysis procedures were utilized to evaluate the future V/C relationships and service level characteristics at each study intersection.

For the two County of Los Angeles study intersections, the significance of the potential project generated traffic impacts was identified using the traffic impact analysis guidelines set forth in the County of Los Angeles Department of Public Works' "Traffic Impact Analysis Report Guidelines", January, 1997. According to the County's published guidelines, the impact is considered significant if the project related increase in the V/C ratio equals or exceeds the following threshold:

	<u>Pre-Project V/C</u>	<u>LOS</u>	<u>Project Related Increase in V/C</u>
•	>0.700-0.800	C	equal to or greater than 0.04
•	>0.800-0.900	D	equal to or greater than 0.02
•	> 0.900	E-F	equal to or greater than 0.01

For the 11 City of Los Angeles study intersections, the significance of the potential project generated traffic impacts was identified using the traffic impact criteria set forth in LADOT's "Traffic Study Policies and Procedures," November, 1993. According to the City's published traffic study guidelines, a significant transportation impact is determined based on the following sliding scale criteria:

	<u>Final V/C</u>	<u>LOS</u>	<u>Project Related Increase in V/C</u>
•	>0.700-0.800	C	equal to or greater than 0.04
•	>0.800-0.900	D	equal to or greater than 0.02
•	> 0.900	E-F	equal to or greater than 0.01

The traffic volumes for each new condition were added to the volumes in the prior condition to determine the change in capacity utilization at the following study intersections:

1. Topanga Canyon Boulevard & Poema Place/Mayan Drive (County)
2. Topanga Canyon Boulevard & SR-118 WB On/Off Ramps (County)
3. Topanga Canyon Boulevard & SR-118 EB On/Off Ramps
4. Topanga Canyon Boulevard & Santa Susana Pass Road
5. Topanga Canyon Boulevard & Chatsworth Street
6. Topanga Canyon Boulevard & Devonshire Street
7. Canoga Avenue & Rinaldi Street
8. Canoga Avenue & Chatsworth Street
9. Canoga Avenue & Devonshire Street
10. De Soto Avenue & SR-118 WB On/Off Ramps
11. De Soto Avenue & SR-118 EB On/Off Ramps
12. De Soto Avenue & Chatsworth Street
13. De Soto Avenue & Devonshire Street

Summaries of the V/C ratios and LOS values during the AM and PM peak hours are shown in Table 5 for the two County of Los Angeles study intersections and are shown in Table 6 for the 11 City of Los Angeles study intersections. Appendix B contains the ICU and CMA data worksheets for the study intersections.

It should be noted that the Mayan Drive/Poema Place and SR-118 Westbound On/Off Ramps intersections with Topanga Canyon Boulevard are within close proximity (i.e., less than 50 feet). Field observations confirm that the movement of traffic of the Mayan Drive/Poema Place intersection which is currently under stop sign control, is highly dependent on the traffic signal operations at the adjacent signalized intersection of Topanga Canyon Boulevard/SR-118 Westbound On/Off Ramps. Therefore, the traffic analysis has assumed that these two intersections function as a single signalized location.

4. Topanga Canyon Boulevard & Santa Susana Pass Road (LOS F - AM Peak Hour, LOS E - PM Peak Hour)
5. Topanga Canyon Boulevard & Chatsworth Street (LOS E - AM/PM Peak Hours)
6. Topanga Canyon Boulevard & Devonshire Street (LOS F - PM Peak Hour)
12. De Soto Avenue & Chatsworth Street (LOS F - AM/PM Peak Hours)
13. De Soto Avenue & Devonshire Street (LOS F - PM Peak Hour)

The remaining study intersections are expected to operate at acceptable Levels of Service (LOS D or better) during both the AM and PM peak hours.

With Related Projects

The City of Los Angeles analysis procedures require that consideration of traffic due to Related Projects to be considered prior to consideration of traffic due to the proposed project. Table 6 shows that the LOS at the study intersections are incrementally increased by the addition of traffic generated by the related projects listed in Table 3. The following eight study intersections are anticipated to operate at LOS E or F during either the AM or PM peak hours with the addition of traffic expected to be generated by the related projects:

3. Topanga Canyon Boulevard & SR-118 EB On-Off Ramps (LOS F - AM/PM Peak Hours)
4. Topanga Canyon Boulevard & Santa Susana Pass Road (LOS F - AM Peak Hour, LOS E - PM Peak Hour)
5. Topanga Canyon Boulevard & Chatsworth Street (LOS E - AM Peak Hour, LOS F - PM Peak Hour)
6. Topanga Canyon Boulevard & Devonshire Street (LOS F - PM Peak Hour)
10. De Soto Avenue & SR-118 WB On/Off Ramps (LOS F - AM Peak Hour)
11. De Soto Avenue & SR-118 EB On/Off Ramps (LOS F - AM Peak Hour, LOS E - PM Peak Hour)
12. De Soto Avenue & Chatsworth Street (LOS F - AM/PM Peak Hours)
13. De Soto Avenue & Devonshire Street (LOS E - AM Peak Hour, LOS F - PM Peak Hour)

It should be noted that all three study intersections located along Canoga Avenue (at Rinaldi Street, at Chatsworth Street, and at Devonshire Street) are projected to continue operating at very good levels of service (LOS A during the AM peak hour and LOS A/LOS B during the PM peak hour), even after the addition of traffic generated by the proposed project.

PROJECT MITIGATION

The traffic analyses in the previous sections determined that development of the proposed Chatsworth Ridge Estates project would generate significant impacts at three intersections. The recommended traffic mitigation program developed for this project includes physical roadway improvements and funding of traffic signals improvements. The following traffic mitigation measures are proposed:

Topanga Canyon Boulevard & SR-118 Freeway WB On/Off Ramps

As previously discussed, the intersections of Topanga Canyon Boulevard at Poema Place/Mayan Drive and Topanga Canyon Boulevard at SR-118 WB On/Off Ramps are closely spaced intersections (i.e., less than 50 feet apart). During the morning and afternoon commute hours, motorists on Poema Place/Mayan Drive accessing Topanga Canyon Boulevard experience long delays due to a lack of traffic signal control at this location. During peak periods, vehicles on the southbound Topanga Canyon Boulevard approach currently queue back onto Poema Place and onto Mayan Drive, and occasionally block vehicles that have the assigned right-of-way through the intersection. Without implementation of the mitigation measures discussed below, this condition would worsen with the buildout of the proposed project and the two proposed related projects located off of Poema Place west of Topanga Canyon Boulevard.

In order to reduce the queuing on Poema Place/Mayan Drive and improve the overall operations at the Topanga Canyon Boulevard terminus area, it is recommended that a traffic signal be installed at the intersection of Topanga Canyon Boulevard and Poema Place/Mayan Drive. The proposed traffic signal will be interconnected and operated in conjunction with the existing traffic signal at

- Widen and restripe the eastbound Poema Place approach to provide a second right-turn lane. This would result in two right-turn lanes (the north right turn lane would also permit through traffic onto Mayan Drive), which will allow significantly more cars to turn southbound through the intersection during each green light phase.

A concept plan of the intersection improvements is provided in Appendix C. The effectiveness of this mitigation measure was assessed through completion of the intersection capacity analyses which assume implementation of the suggested mitigation measure (i.e., new traffic signal, signals modification/coordination, intersection widening and restriping). As shown in Table 5, with the proposed mitigation measures, the significant impact is expected to be fully mitigated.

In addition to the analysis summarize in Table 5, which demonstrates that the recommended traffic improvements will mitigate the project-related traffic impacts to levels of insignificance, additional performance measures were determined to measure the effectiveness of the mitigation for local residents who currently travel through the Topanga Canyon Boulevard terminus area during peak hours. Table 7 provides a summary of vehicle queue and delay values for three critical movements at the Topanga Canyon Boulevard intersection that control the flow of traffic to and from the existing residential areas located north of the freeway: the eastbound Poema Place approach, the westbound Mayan Drive approach (which will be A Street in the future condition with the proposed project), and the SR 118 westbound off-ramp. Table 7 also provides the calculated Levels of Service for these individual approaches, which differs from the service levels reported in Tables 5 and 6 which report Levels of Service for the entire intersection (i.e., the average Level of Service of all movements at the intersection). The vehicle queue and delay was calculated for existing conditions, future pre-project conditions, and future with project conditions (i.e., future conditions with project-related traffic and implementation of the recommended traffic improvements). The vehicle queue and delay values in Table 7 were calculated using the Synchro Version 5.0 software package, which is based on the *2000 Highway Capacity Manual* published by the Transportation Research Board.

As shown in Table 7, motorists exiting the existing residential areas north of the freeway on Poema Place and Mayan Drive experience LOS E conditions during the AM peak hour, with calculated average delays of over 75 seconds per vehicle. In the future pre-project condition, average delays are expected to worsen substantially during the AM peak hour (approximately 194 seconds for Poema Place and 105 seconds for Mayan Drive), resulting in LOS F conditions.

For the SR 118 westbound off-ramp, motorists currently returning home during the PM peak hour experience LOS E conditions with an average delay of 76 seconds per vehicle. In the future pre-project condition, average delays will also worsen during the PM peak hour to approximately 144 seconds, resulting in LOS F conditions.

Table 7 shows that implementation of the proposed project substantially improves the delay and service levels on the key approaches. That is, while the proposed project will result in additional trips at the intersection, construction of the recommended roadway and traffic signal improvements will not only accommodate project-related traffic, but also mitigate a portion of the current and future traffic congestion that is not related to or caused by the project. For motorists exiting the residential areas north of the freeway during the AM peak hour, LOS A conditions are calculated for Poema Place, and LOS D conditions are calculated for the future A Street during the AM peak hour. Average delay values are calculated to be substantially improved as compared to current and future pre-project conditions. For residents returning home in the PM peak hour, the SR 118 westbound off-ramp is calculated to operate at LOS D with average delay values also substantially improved as compared to existing and future pre-project conditions.

To summarize, the recommended traffic mitigation measures at the Topanga Canyon Boulevard terminus area provide significant improvements to traffic flow based on the following:

- The incorporation of the Poema Place and Mayan Drive/A Street approaches within the overall traffic signal control of the intersection substantially improves the efficiency (and safety) of traffic movements to and from these streets.

According to Section D.9.1 (Appendix D page D-6) of the 1997 CMP manual, the criteria for determining a significant impact are as follows:

“For the purpose of a CMP TIA, a significant project impact occurs when the proposed project increases traffic demand on a CMP facility by 2% of capacity ($V/C \geq 0.02$), causing or worsening LOS F ($V/C > 1.00$). The lead agency may apply more stringent criteria if desired.”

The CMP significant impact criteria apply for analysis of both intersection and freeway monitoring locations.

CMP Intersections

According to the CMP, the following are CMP monitoring stations located in the project vicinity:

- Topanga Canyon Boulevard & SR-118 Westbound On/Off Ramps
- Topanga Canyon Boulevard & Devonshire Street

The intersection of Topanga Canyon Boulevard and SR-118 Westbound On/Off Ramps was evaluated using the ICU method and the intersection of Topanga Canyon Boulevard and Devonshire Street was evaluated using the CMA method. Both methods determine the V/C ratio on a critical lane basis. The overall intersection V/C ratio is subsequently assigned an LOS value to describe intersection operations. The LOS values vary from LOS A (free flow) to LOS F (jammed condition). Appendix B provides a description of both the ICU and CMA methods and their corresponding LOS.

Levels of service were determined at the CMP intersections for the conditions listed above in the Traffic Impact Analysis Scenarios section. The ICU and CMA data worksheets contained in Appendix B were also utilized for this analysis. A summary of the V/C ratios and LOS values for the CMP intersections during the AM and PM peak hours is presented in Tables 5 and 6.

Based on the guidelines set forth in Appendix D of the CMP (Guidelines for CMP Transportation Impact Analysis), a factor of 1.4 is used to convert vehicle trips to persons trips. Furthermore, the total person trips were multiplied by 3.5 percent (for each time period), since the criteria for CMP transit centers and transit corridors were not met. The converted transit person trips were calculated as follows:

Daily Transit Person Trips = $4,874 \times 1.4 \times 3.5\% = 239$ Person Trips

AM Peak Hour Transit Person Trips = $387 \times 1.4 \times 3.5\% = 19$ Person Trips

PM Peak Hour Transit Person Trips = $489 \times 1.4 \times 3.5\% = 24$ Person Trips

As a result, the existing transit service demand could be increased by up to 19 and 24 persons during the AM and PM peak hours, respectively, due to development of the proposed residential project. In addition, a total of 239 daily persons trips on the public transit are forecasted.

Based on the number and frequency of transit services provided in the project vicinity (discussed in a previous section), the additional bus ridership due to the project is not expected to have a significant impact on the public transit system.

NEIGHBORHOOD PROTECTION PLAN

Based on discussion with City staff, the City of Los Angeles is planning to implement a neighborhood protection plan to an area located approximately 1.5 miles south of the proposed project site. This area is bounded by Chatsworth Street to the north, Devonshire Street to the south, Canoga Avenue to the east, and Topanga Canyon Boulevard to the west. The purpose of this program is to discourage cut-through traffic from using Owensmouth Avenue by restricting left-turn movements at the Owensmouth Avenue intersections at Chatsworth Street and at Devonshire Street.

Based on the neighborhood protection measures proposed for Owensmouth Avenue, this traffic analysis has been prepared based on the assumption that project related traffic will not utilize Owensmouth Avenue between Chatsworth Street and Devonshire Street. Thus, no project related impacts would result on Owensmouth Avenue south of Chatsworth Street.

6. Topanga Canyon Boulevard & Devonshire Street
13. De Soto Avenue & Devonshire Street

Also, additional mitigation measures beyond those discussed under the Project Mitigation section will be required for two of the three impacted intersections to offset the residual impact caused by the additional number of residential units under this alternative.

The Existing Zoning Alternative

Under this alternative, the existing 2,443 Record of Survey lots would be merged into 634 lots with Certificates of Compliance. Each merged lot would be a minimum of 6,000 square feet in size, thereby making it consistent with existing, underlying R1-6000 zoning for all of the property. From a traffic standpoint, the additional number of residential dwelling units will result in significant project impacts at other study intersections. In addition to the three significant impacts identified previously, the following three study intersections will likely be impacted under this alternative:

4. Topanga Canyon Boulevard & Santa Susana Pass Road
6. Topanga Canyon Boulevard & Devonshire Street
13. De Soto Avenue & Devonshire Street

Also, additional mitigation measures beyond those discussed under the Project Mitigation section will be required for two of the three impacted intersections to offset the residual impact caused by the additional number of residential units under this alternative.

The Reduced Density Alternative

Under this alternative, some of the lot size will be increased from their minimum to reduce the visual impact of the project from the adjacent hiking trails. Under this alternative, some residential lots along Devil's Canyon would be eliminated. The number of residential dwelling units under this alternative will be reduced to a maximum of up to 517 units. From a traffic standpoint, the same number of impacted intersections previously identified for the proposed project would result under

Linscott, Law & Greenspan, Engineers

APPENDIX B

**Levels of Service Explanation
and
ICU / CMA Data Worksheets - AM and PM Peak Hours**

INTERSECTION CAPACITY UTILIZATION (ICU) DESCRIPTION

Level of Service is a term used to describe prevailing conditions and their effect on traffic. Broadly interpreted, the Levels of Service concept denotes any one of a number of differing combinations of operating conditions which may occur as a roadway is accommodating various traffic volumes. Level of Service is a qualitative measure of the effect of such factors as travel speed, travel time, traffic interruptions, freedom to maneuver, safety, driving comfort and convenience.

Six Levels of Service, A through F, have been defined in the 1965 *Highway Capacity Manual*, published by the Transportation Research Board. Level of Service A describes a condition of free flow, with low traffic volumes and relatively high speeds, while Level of Service F describes forced traffic flow at low speeds with jammed conditions and queues which cannot clear during the green phases.

The Intersection Capacity Utilization (ICU) method of intersection capacity analysis has been used in our studies. It directly relates traffic demand and available capacity for key intersection movements, regardless of present signal timing. The capacity per hour of green time for each approach is calculated based on the methods of the *Highway Capacity Manual*. The proportion of total signal time needed by each key movement is determined and compared to the total time available (100 percent of the hour). The result of summing the requirements of the conflicting key movements plus an allowance for clearance times is expressed as a decimal fraction. Conflicting key traffic movements are those opposing movements whose combined green time requirements are greatest.

The resulting ICU represents the proportion of the total hour required to accommodate intersection demand volumes if the key conflicting traffic movements are operating at capacity. Other movements may be operating near capacity, or may be operating at significantly better levels. The ICU may be translated to a Level of Service as tabulated below.

The Levels of Service (abbreviated from the *Highway Capacity Manual*) are listed here with their corresponding ICU and Load Factor equivalents. Load Factor is that proportion of the signal cycles during the peak hour which are fully loaded; i.e. when all of the vehicles waiting at the beginning of green are not able to clear on that green phase.

Intersection Capacity Utilization Characteristics

Level of Service	Load Factor	Equivalent ICU
A	0.0	0.00 - 0.60
B	0.0 - 0.1	0.61 - 0.70
C	0.1 - 0.3	0.71 - 0.80
D	0.3 - 0.7	0.81 - 0.90
E	0.7 - 1.0	0.91 - 1.00
F	Not Applicable	Not Applicable

SERVICE LEVEL A

There are no loaded cycles and few are even close to loaded at this service level. No approach phase is fully utilized by traffic and no vehicle waits longer than one red indication.

SERVICE LEVEL B

This level represents stable operation where an occasional approach phase is fully utilized and a substantial number are approaching full use. Many drivers begin to feel restricted within platoons of vehicles.

SERVICE LEVEL C

At this level stable operation continues. Loading is still intermittent but more frequent than at Level B. Occasionally drivers may have to wait through more than one red signal indication and backups may develop behind turning vehicles. Most drivers feel somewhat restricted, but not objectionably so.

SERVICE LEVEL D

This level encompasses a zone of increasing restriction approaching instability at the intersection. Delays to approaching vehicles may be substantial during short peaks within the peak hour, but enough cycles with lower demand occur to permit periodic clearance of queues, thus preventing excessive backups. Drivers frequently have to wait through more than one red signal. This level is the lower limit of acceptable operation to most drivers.

SERVICE LEVEL E

This represents near capacity and capacity operation. At capacity (ICU = 1.0) it represents the most vehicles that the particular intersection can accommodate. However, full utilization of every signal cycle is seldom attained no matter how great the demand. At this level all drivers wait through more than one red signal, and frequently through several.

SERVICE LEVEL F

Jammed conditions. Traffic backed up from a downstream location on one of the street restricts or prevents movement of traffic through the intersection under consideration.

Crit. Volumes:	N-S: 1083	E-W: 659	SUM: 1742	N-S: 1191	E-W: 725	SUM: 1916	N-S: 1309	E-W: 780	SUM: 2089	N-S: 1309	E-W: 780	SUM: 2089	N-S: 1411	E-W: 780	SUM: 2191
No. of Phases:	3			3			3			3			3		
Volume / Capacity:	1.222			1.345			1.466			1.466			1.538		
Level of Service:	F			F			F			F			F		F

Assumptions:
 Maximum Sum of Critical Volumes (Intersection Capacity): 2 Phase=1500, 3 Phase=1425, 4+ Phase=1375.
 For dual turn lanes, 55% of volume is assigned to heavier lane.
 For one excl. and one opt. turn lane, 70% of volume is assigned to exclusive lane.
 Right turns on red from excl. lanes = 50% of overlapping left turn.
 * V/C ratio reduced by 0.07 to reflect contribution to the City's ATISAC system.

**Las Virgenes Municipal Water District
Water System Design Report
for
Tentative Tract No. 53138
Chatsworth Ridge
Los Angeles County, California**

Section 1 - Introduction

Tentative Tract No. 53138 is located on approximately 238 acres in the hills northeast of the Topanga Canyon Blvd. interchange with California Highway 118 (Simi Valley Freeway) in Los Angeles County, California. The development of 537 single-family residential lots is proposed for Tract No. 53138.

The purpose of this Water System Design Report is to investigate the feasibility of providing potable water service to Tentative Tract No. 53138, and to develop criteria for the facilities required to provide adequate service. Potable water demand for the proposed development is based on the "Potable Water System Master Plan for the Las Virgenes Municipal Water District," Boyle Engineering Corporation, (Ref. 1). Fire protection requirements are as determined by the Los Angeles County Fire Department.

The owner and developer of Tentative Tract No. 53138 is Presidio Chatsworth Partners, LLC, 495 Market St, Suite 2400, San Francisco, CA, 94105.

The developer's engineer is B & E Engineers, 24 W. St. Joseph Street, Arcadia, California 91007-2854, (626) 446-4449.

Section 3 - Potable Water Demand

The potable water demand estimated for the proposed development is shown in **Table 1**. Demand will be generated by residential use and by irrigation of landscaped cut and fill areas. The average daily demand presented in Reference 1 for medium density residential use in this area of Los Angeles County is 100 gpd/person. This demand factor is based on historical usage. Existing medium density residential developments in the area include small residential lots with little landscaping. Consequently, the demand factor presented in Reference 1 is lower than demand factors for medium density residential use in other areas within the District. In order to project the potable water demand for the proposed development accurately, an average daily demand of 250 gpd/person was used. This demand factor is more typical of other new medium-density residential developments throughout the District.

Extensive grading is proposed as part of the development of Tract 53138. Approximately 39.9 acres of cut and fill slopes will be landscaped and irrigated. These slopes will be irrigated and maintained by a homeowner's association. Irrigation demand for cut and fill slopes was estimated based on an application rate of 3 feet of water per year.

Section 4 - Existing Potable Water System

Tentative Tract No. 53138 will be served from the District's nominal 1585-foot gradient Twin Lakes Subsystem. At present, the 1585-foot Twin Lakes Subsystem is isolated from the rest of the District. The MWDSC LV-3 turnout, located just below the Twin Lakes Pump Station, delivers water to the pump station at a maximum gradient of approximately 1265 feet.

The Twin Lakes Pump Station includes 4 pumps with a total capacity of 2050 gpm. Currently three pumps operate. A fourth pump is provided for standby capacity. The pump station maintains the gradient in the Twin Lakes Tanks (HWL=1585 feet). The tanks have a combined capacity of 2.0 MG.

The existing pump station and tanks exceed the capacities required by the existing demand in the Twin Lakes Subsystem (see Reference 3). The total projected demand within the Twin Lakes Subsystem after the development of Tentative Tract No. 53138 is shown in **Table 2**. With the development of Tentative Tract No. 53138, the projected demand will require a storage capacity of 1.99 MG and a pumping capacity of 1972 gpm. These calculations are based on 18-hr. pumping as recommended in Reference 1. The existing pump station and tanks have the capacity to accommodate the new development, but the additional demand from this development will require nearly all of the current excess pumping and storage capacity. Any future development in the area will require additional storage and pumping facilities. Also, the meter at the LV-3 turnout currently limits flow to 1800 gpm. A new meter will be required at LV-3 as this development and other developments are built.

The current and previous Master Plans for the District have assumed that much of this area would need to be serviced from a new higher pressure zone, with new pumping and storage facilities. These Master Plans were based on general assumptions regarding pressure losses and available topographic maps that were not precise enough to draw a fine-line boundary for the existing Twin Lakes pressure zone. The more detailed analysis performed for this system design report indicates that new storage facilities are not needed for this tract. Demand at the higher lots within the development can be met by creating a small zone of higher pressure using a hydropneumatic pump station within the new development.

Creating a hydropneumatic pressure zone would increase pressures at the higher services, but would not relieve the pumping and storage requirements placed on the existing system by the new development.

Section 5 - Proposed Potable Water System

The proposed potable water system, necessary to serve Tentative Tract No. 53138 is shown on **Plate 2**. The Los Angeles County Fire Department has determined that the development will require 44 new fire hydrants, located throughout the development as shown on **Plate 2**. These hydrants shall conform to AWWA Standard C503 with 6"x 4"x 2-1/2" bronze heads. The minimum flow required is 1250 gpm for 2 hours. The proposed system will be capable of providing fire flow to all hydrants at pressures greater than the current required minimum residual pressure of 20 psi.

The California State Department of Health Services has proposed changes to Title 22 of the State Code which would require the minimum pressure at service connections to be 30 psi, except in times of emergency. Conversations with DHS officials indicate that most fires would not be considered emergencies (only fire storms). Definitely, the filling of a water truck would not be considered an emergency. The analysis that is summarized in **Table 3** indicates that this development would comply with the proposed code changes.

The proposed water system will deliver water to Tract 53138 directly from the existing Twin Lakes Tanks. This will require the construction of a 16-inch pipeline, connecting the proposed water system directly to the Twin Lakes Tanks, with no connections in between. The pipeline must be no higher than the bottom elevation of the larger Twin Lakes Tank (1555 feet).

According to the calculation shown in **Table 2**, during a day of peak use the water demanded from the tank will be as much as 914,020 gallons. This indicates that on a day of peak water demand, without any fires or emergencies, the water level in the tank will drop down to 1571.5 feet. According to the developer's grading plan, several lots are planned above 1470 feet. Even with oversized piping throughout the development, several homes could expect to have pressures lower than 43-psi at their service connections.

In order to provide these homes with minimum pressures of at least 43-psi at their service connections, as required in the District's potable water ordinance, it is recommended that a small pump station with a hydropneumatic tank be installed. The recommended location of the pump station is the lot at the corner of "C" street and "T" street, as shown on **Plate 2**. The pump station would include 2 pumps,

Pipes in the system were sized to transmit fire flows, without the pump station operating, to each hydrant with a minimum residual pressure well in excess of the 20-psi required by the Los Angeles County Fire Department. The pipes were also sized to transmit peak hour demands, with the pump station operating, while maintaining a pressure of at least 43-psi at each service connection.

There is a remote possibility of future development within the District's service boundary in the area north of Tract 53138. However, the terrain, elevation, and location of this property, along with environmental concerns, suggest that the likelihood of development is very remote. Access to the property through Tract 53138 would be unlikely because of steep slopes and rugged terrain. Because development is unlikely in this area, and would probably not be accessed through Tract 53138, the proposed facilities needed to serve Tract 53138 were not sized to serve this or any other future developments.

Hydraulic gradients and pressures expected at key locations within Tract 53138 during various demand conditions are shown in Table 3. Six units with service connections in the 1585-ft pressure zone are below an elevation of 1239 feet and will experience maximum pressures greater than 150-psi. These units are all located on the cul-de-sac at the south end of "B" street. Pressure reducing valves will need to be installed on the District's side of each of these meters, in order to assure that the meters are not damaged.

All units with service connections within the 1585-ft zone below an elevation of 1398 feet will experience maximum pressures greater than 80-psi. These units will require individual pressure regulators ahead of the building plumbing to limit pressures to not more than 80-psi, as required by the Uniform Plumbing Code. All units in the 1656-ft pressure zone below an elevation of 1471 feet will experience maximum pressures greater than 80-psi and will also require pressure regulators ahead of the building plumbing.

Section 6 - Recycled Water

There are currently no reclaimed water facilities adjacent to the proposed development. The development is located in the northeast corner of the District's service area, far from any of the District's reclaimed water facilities. The development will include 39.9 acres of irrigated cut and fill slopes, which would be available to receive reclaimed water for irrigation. However, a connection to the District's reclaimed water system would be impractical and so the cut-and-fill slopes will be irrigated with potable water as discussed in the previous sections.

Section 7 - Sewer System

Tentative Tract No. 53138 is not presently located within the Las Virgenes Municipal Water District's service area and has not been annexed to a Sanitation Improvement District. The District will need to create a new Sanitation Improvement District or extend the existing Sanitation Improvement District B to include the new development. Sanitation Improvement District B presently covers only those areas west of Topanga Canyon Blvd. The estimated average daily sewage that will be generated by Tract 53138 is shown in **Table 4**.

TABLE 4
Sewage Generation

Land Use	Units	Daily Generation Rate (gallons/unit)	Daily Total (gallons)
Residential	537	350	187,950

This development is located in an area that is not within reach of the District's sewerage collection facilities. The City of Los Angeles is under agreement with the Las Virgenes Municipal Water District to convey and treat sewage from developments in the area. Under this agreement, the District is required to pay the City of Los Angeles for conveyance, treatment and applicable charges related to new development. The district recovers these costs from sewer service and capital facilities charges to the new development.

The City also requires metering of flows into their sewer system above 0.3 cfs (193,880gallons/day). Because the estimated daily sewage generated by the development is nearly 0.3 cfs, the developer will be required to install a meter at the point of connection to the City of Los Angeles sewer system to ensure that this part of the agreement is met.

Section 8 - Construction Phasing and Acceptance

The public water facilities of Tentative Tract No. 53138 will be constructed in two phases. The first phase will include the construction of the southern half of the development, as seen in **Plate 2**. Homes built in the first phase of development will all be served from the existing Twin Lakes pressure zone. The second phase of the project will include the northern half of the development. The construction of the pump station and homes served by the higher pressure zone will be included in the second phase.

In accordance with standard policy, the District will consider final acceptance of the potable water systems when a previously defined, separately bonded phase of the project is completed. This will minimize administration problems and allow the developer the flexibility in planning and phasing the project without the responsibility of providing on-going water service to sold lots until the entire project is completed. Construction shall be considered complete for a phase when all facilities related to the potable water systems have been installed in accordance with the District's standards and the approved water system design report, and all meter boxes have been set to grade in concrete sidewalks.

The developer must comply with the Special Conditions for bonds, temporary risers and hose bibs, and repair of damage to accepted water system components set forth in the District's memorandum entitled, "Review of Policy - Acceptance of Tract Water Systems (July 14, 1989)."

Section 9 - Water Conservation

In accordance with District Water Ordinance 11-86-161, the following water conservation measures are required:

- Waste and leakage of water is not allowed.
- For residential development, all toilets installed shall use 1.6 gallons or less per flush, and all showerheads shall flow at 2.5 gallons per minute, or less, at 80 psi.

In addition, if a model home display is to be provided, one of the models must be landscaped with water efficient (Xeriscape) plant materials and irrigated with an appropriate water conserving irrigation system. Further, the Xeriscape model shall be designed to be drought tolerant; irrigation intensive plants are discouraged. Turf shall occupy no more than 30% of the landscaping. The model home display shall draw attention to the specific landscape materials and irrigation techniques utilized.

To obtain maximum benefit of the limited water resources of the State of California, Las Virgenes Municipal Water District has adopted landscape ordinances that require plant materials and irrigation systems to be water efficient. In accordance with District Ordinance No. 1-93-205, landscape and irrigation plans must be submitted to the District for review. The landscape and irrigation plans must be in conformance with District landscaping and irrigation specifications as contained in the Las Virgenes Municipal Water District Landscaping Guide.

Section 10 - Financial Impact On District

The new water system facilities required to serve Tentative Tract No. 53138 are for the benefit of the proposed development and provide no significant benefit to the existing District system. Therefore, no District financial participation in new water system facilities related to Tract 53138 is warranted under District Rules and Regulations. The developer is therefore responsible for funding all of the new in-tract potable waterlines and appurtenances

Section 11 - Environmental Review

The District is a "responsible agency" for the purpose of environmental review of this project under the California Environmental Quality Act (CEQA). The lead agency for the environmental review of this project under the CEQA is the County of Los Angeles, Department of Regional Planning.

The County of Los Angeles Board of Supervisors at its meeting on _____ did certify the Final Environmental Report including addenda for Tract 53138. Minutes of that meeting and attached documents are included in Appendix "A" of this report.

Additional documentation, in compliance with CEQA, will be prepared for the pump station by the District, prior to its construction.

Section 12 - Conclusions And Recommendations

A. It is concluded that:

1. To provide adequate potable water service to the proposed development, the following facilities must be installed by the developer:
 - a) The water mains and appurtenances shown on **Plate 2**, including a dedicated 16-inch pipeline connecting the Twin Lakes Tanks directly to the new development. This study does not address in detail the routing of this pipe.
 - b) Forty-four new fire hydrants.
 - c) A pump station, including 2 pumps capable of delivering 1350 gpm at 50 feet of head, and a 14,250 gallon hydropneumatic tank, as shown on **Plate 2**.
2. A new meter will be required at the LV-3 turnout to supply the increasing demands produced by this and other developments.
3. Six units within Tract 53138 served by the 1585-ft pressure zone that are below elevation 1239 feet will experience pressures in excess of 150-psi. For these units, pressure-reducing valves will be required on the District side of the meters.
4. All units served by the 1585-ft pressure zone below 1398 feet will experience pressures in excess of 80-psi. All units served by the 1656-ft pressure below 1471 feet will experience pressures in excess of 80-psi as well. Each of these service connections will require an individual pressure regulator ahead of building plumbing in accordance with the 80-psi limitation imposed by the Uniform Plumbing Code.
5. All potable water system improvements served by the 1585-ft pressure zone should be designed to accommodate hydraulic gradients not less than 1585 feet. All potable water system improvements served by the 1656-ft pressure zone should be designed to accommodate hydraulic gradients not less than 1656 feet.

3. The District require all above-ground District-owned facilities (i.e. meters larger than 2 inches, detector check installations, and backflow prevention devices) be installed above ground and screened from view in accordance with District standard plans.
4. The Board determine that no District financial participation in new off-site water system facilities related to of Tentative Tract No. 53138 is warranted.
5. The projects' Mitigated Negative Declaration (MND) prepared by the _____ and _____ Resolution No. _____ approving the project be accepted and utilized by the District, and the Secretary be directed to file a Notice of Determination which reflects the foregoing.
6. Additional documentation in compliance with CEQA be prepared for the pump station.

Section 13 - Limitations

Report Intent. This Water System Design Report is intended only to develop the hydraulic information necessary to design a water system. No effort has been made at this time to precisely locate existing or proposed facilities. Conflicts may develop as more information is discovered about both existing and proposed pipelines, street grades, etc. Corrections of conflicts related to this project will be the responsibility of the applicant.

Project Changes. This Water System Design Report is based upon maps of Tract 53138 prepared by B & E Engineers, County of Los Angeles Planning Commission Resolution _____, and upon information submitted by the developer of the subject property and his representatives. Accordingly, this design report may be subject to modification to reflect changes made by the applicant. This report may also be subject to modification to reflect additions or amendments to the District's Water Ordinance and the District's Design Standards prior to approval of the final design. Any revision in the above information or development map or deviation therefrom may invalidate the conclusions and recommendations. A supplemental or amended report must be prepared for the use of the District at the applicant's sole expense if the project or the data is changed.

Other Agency Approvals. This Water System Design Report has been prepared at the request of the developer of Tract 53138. Approval of this report does not indicate the District either supports or opposes the underlying project or any related project. District staff will answer questions concerning this report. However, the project proponent is solely responsible for securing necessary project approvals from state, regional, and local agencies with jurisdiction by law without the express or implied intervention or support of the District.

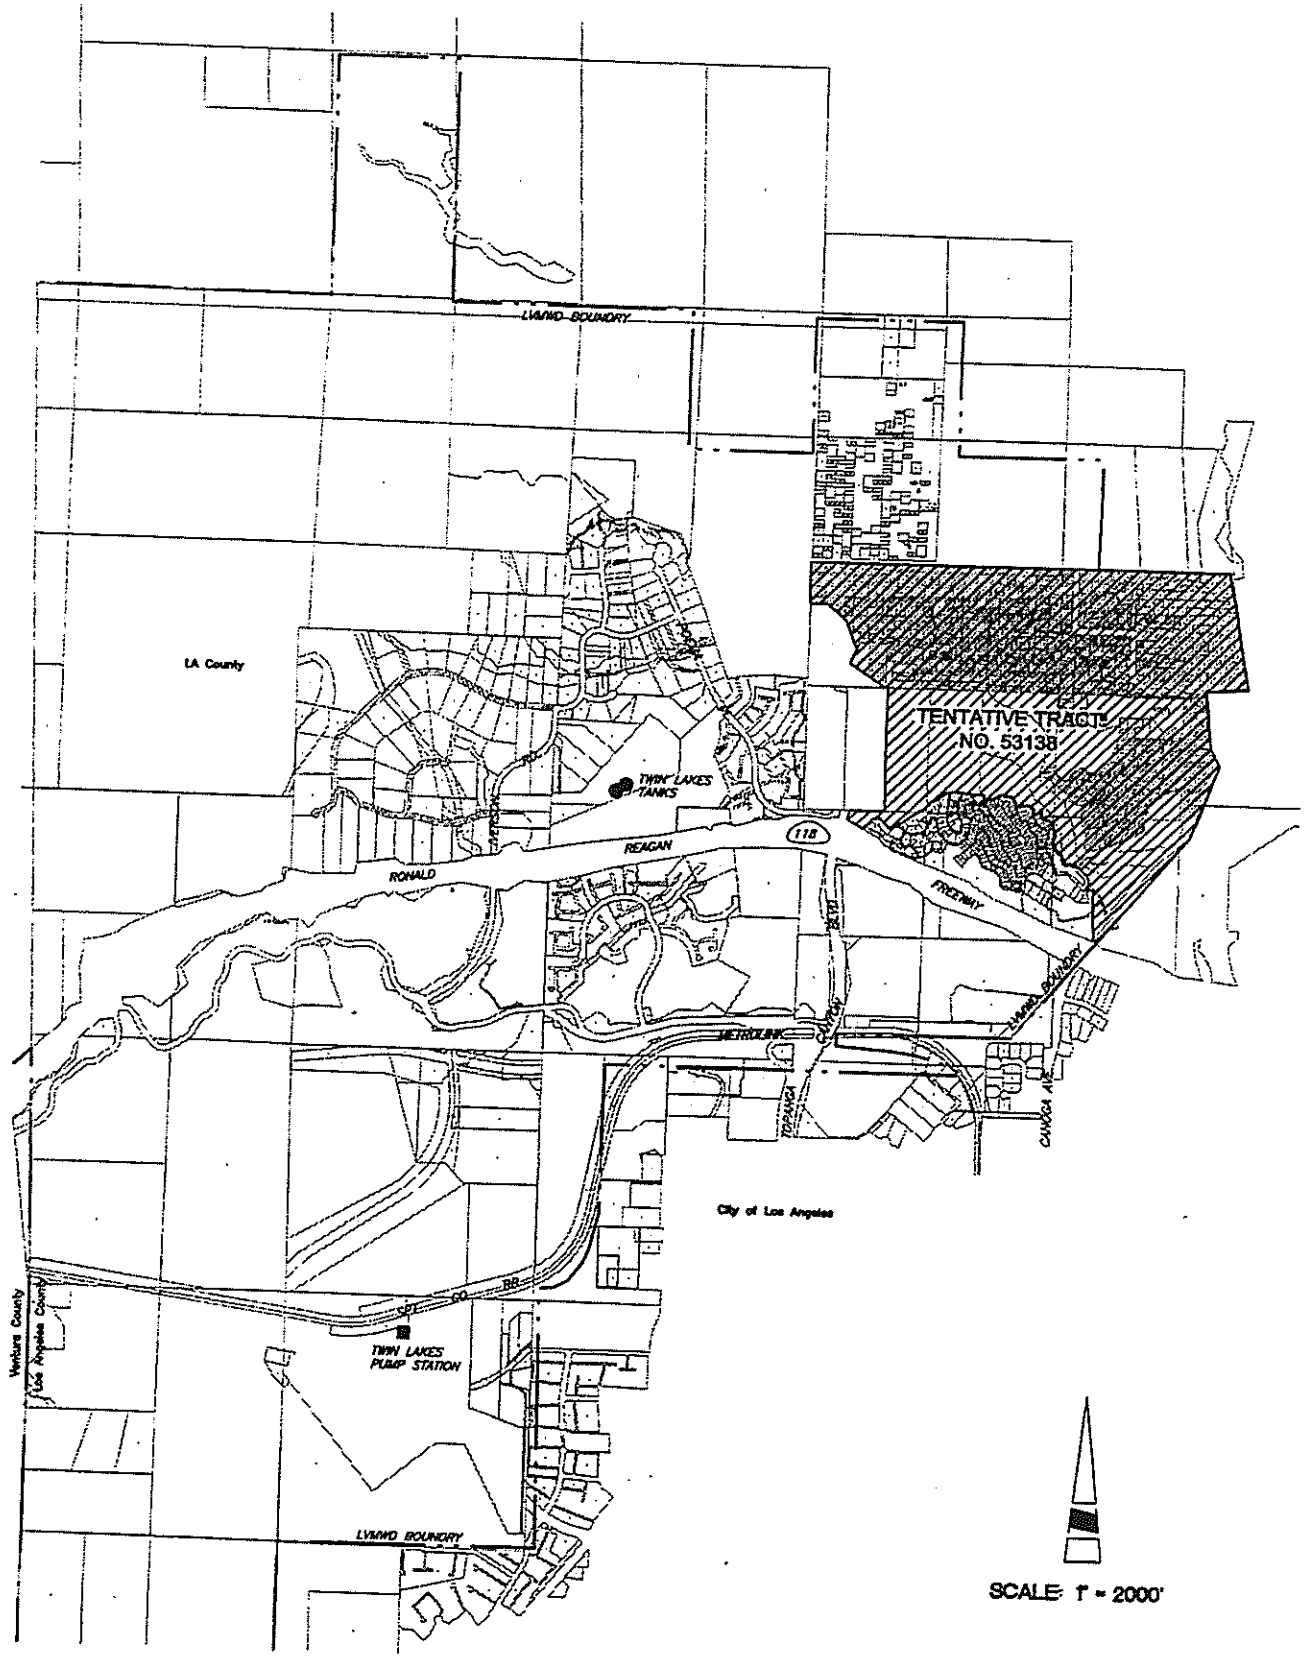

Project Delays. This Water System Design Report is based upon the assumption that the project will be implemented in due course. A supplement, amendment or complete report must be prepared for the use of the District at the proponent's sole expense if the project is unduly delayed.

Warranty of Supply. The approval of this Water System Design Report does not constitute a commitment by the District to supply water or provide sanitation service to the project. The project will be assured of connection to the water and sanitation systems of the District only if the proponent also

Calabasas, CA. 91302
ATTN: Hans Girard

Subject: Tract 53138, Chatsworth

Dear Hans

We have been requested to advise you that Southern California Edison Company stands ready to install electrical distribution facilities within the subject area in accordance with the then applicable tariff schedules which are the effective rates and rules of Southern California Edison Company on file with and approved by the California Public Utilities Commission and subject to the receipt of such permits or other authorizations from public agencies as may be required for such installation. Also, rules hereinafter referred to in this letter include such changes, modifications, and amendments which the Public Utilities Commission may from time to time direct in the exercise of its jurisdiction.

Should a shortage of energy and/or generating capacity ever occur, the utility will apportion its available supply of electricity among its customers as set forth in Rule No. 14, Shortage of Supply and Interruption of Delivery.

When requested by the developer or individual applicant, extension of facilities within or to reach the tract or parcel require advances under provisions set forth in Rule No. 15. An underground service lateral from the installed underground distribution system within the development to individual parcels will be in accordance with Rule No. 16.

Should an individual applicant require service to his parcel prior to the installation of an underground distribution system to and within the development, as may be installed at the expense of a developer, or within a development for which the developer has undertaken no obligation for the installation of an underground distribution system, an advance will be required from the individual as set forth in Rule No. 15.

Sincerely,

Alan A. Ito

EXECUTIVE SUMMARY

DEMAND OUTLOOK

California natural gas demand, including volumes bypassing utility systems, is expected to grow at an annual average rate of 0.5% from 2000 to 2020. This forecast is consistent with projections of population and employment growth rates.

Load growth of approximately 1% is expected for the Residential and Commercial and sectors, and more modest growth of 0.6% is estimated for the industrial sector.

Electric Generation (EG) demand is expected to decline due to more electric power generation outside of the state and efficiencies in the operation of gas fired generators. The NGV market continues to have the highest growth potential due to an optimistic assessment of the changing regulatory environment associated with anticipated clean air policies over the next two decades.

GAS STRATEGY

In January 1998, the Commission opened an Order Instituting Rulemaking (R.98-01-011) to assess the natural gas regulatory and market framework and to adopt market-oriented reforms. In July 1999, the Commission issued a decision identifying various promising options for changing the natural gas regulatory structure and opened a companion Order Instituting Investigation (I.99-07-003) to consider the costs and benefits of these promising options.

In Northern California, many of the promising options were already incorporated in PG&E's Gas Accord Settlement, implemented in March 1998. The remaining promising options were addressed in two settlements, which were filed with the Commission in October 1999 and January 2000, and approved by the Commission in decisions issued in January 2000 and May 2000.

In Southern California, various settlements were filed with the Commission between December 1999 and April 2000. These settlements were the subject of evidentiary hearings which concluded in June 2000. A Commission decision is expected by early 2001.

FOCUS ON EFFICIENCY AND ENVIRONMENTAL QUALITY

California utilities continue to focus on Customer Energy Efficiency (CEE) and other Demand-Side Management (DSM) programs in their utility electric and gas resource plans.

In addition, California utilities actively support Clean Air Act amendments that seek to improve air quality by reducing fuel oil use in electric generation power plants and by marketing natural gas vehicles.

The increasing awareness of natural gas as a clean, economical fuel continues to help position utilities to meet environmentally acceptable energy requirements of the future.

SUPPLY OUTLOOK/PIPELINE CAPACITY

California's existing gas supply portfolio is regionally diverse and includes supplies from California sources (onshore and offshore), Southwestern U.S. supply sources (the Permian, Anadarko, and San Juan Basins), the Rocky Mountains, and Canada. The map on the following page shows the locations of these supply sources and of the natural gas pipelines serving California.

Additional pipeline capacity and open access have contributed to long term supply availability and gas-on-gas competition. Interstate pipelines currently serving California include El Paso Natural Gas Company (El Paso), Kern River Transmission Company (Kern River), Mojave Pipeline Company (Mojave), PG&E Gas Transmission-Northwest (PG&E GT-NW), Transwestern Pipeline Company (Transwestern), and Tuscarora Pipeline.

INTRODUCTION

Southern California Gas Company (SoCalGas) is the principal distributor of natural gas in southern California, providing retail and wholesale customers with procurement, transportation, exchange and storage services. SoCalGas is a gas-only utility and, in addition to serving the residential, commercial, and industrial markets, provides gas for enhanced oil recovery and electric generation in southern California. San Diego Gas & Electric Company (SDG&E), Southwest Gas Corporation, and the City of Long Beach Gas and Electric Department are SoCalGas' three wholesale utility customers. Gas service at wholesale is expected to begin to the City of Vernon during the forecast period.

This report covers a 20-year forecast period, from 2000 through 2020; only the consecutive years 2000 through 2006 and the point years 2010, 2015 and 2020, however, are shown in the tabular data in the next sections. The forecast is subject to uncertainty, but represents SoCalGas' best estimates for the future, based upon the most current information available.

The Southern California section of the 2000 California Gas Report begins with a discussion of the economic conditions and regulatory issues facing the utilities, followed by a discussion of the factors affecting gas demand in various market sectors. The outlook on gas supply availability, which continues to be favorable, is presented next. SoCalGas' weighted average cost of gas (WACOG) price forecast is discussed followed by a review of the peak day demand forecast. Summary tables and figures underlying the forecast are provided.

CAPACITY, SOURCES, AND STORAGE

INTERSTATE PIPELINE CAPACITY

Southern California continues to operate in an environment of excess interstate pipeline capacity. Interstate pipeline delivery capability into southern California is over 4,000 MMcf/day, with approximately 3,230 MMcf/day available directly to SoCalGas customers (the remaining interstate capacity serves local distribution company bypass customers). These pipeline systems provide access to several large supply basins, located in: New Mexico (San Juan Basin), West Texas (Permian Basin), Rocky Mountains and Western Canada. The interstate pipeline systems, along with local California gas supplies, deliver gas to most southern California customers through SoCalGas.

The following interstate pipeline volumes and local production can be delivered to SoCalGas customers on a firm basis using intrastate transmission capacity:

Interstate and Local Volumes MMcf/day

Current Firm Capacity ⁽³⁾	
El Paso at Blythe	1,210
El Paso at Topock	540
Transwestern at Needles	750
Mojave at Hector Road ⁽⁴⁾	50
PG&E, Kern/Mojave & OXY at Wheeler Ridge	680
Existing Firm Intrastate Capacity	3,230
California Production ⁽⁵⁾	270
Total Firm Supply Access	3,500

Gas industry restructuring (GIR) proposals pending before the Commission for SoCalGas customers may unbundle local distribution company intrastate transmission capacity by creating tradable firm intrastate capacity rights.

³ Firm Capacity with matching intrastate capacity only. Does not include interruptible or excess upstream capacity. An additional 700 MMcf/day is available directly to southern California customers from the Kern River and Mojave pipelines.

⁴ Hector Road will become a formal receipt point as part of GIR.

⁵ California production available to SoCalGas customers via Line 85 and the North Coastal system.

GAS SUPPLY SOURCES

Southern California receives gas supplies from several sedimentary basins in the western United States and Canada.

California Gas

Gas supply available to SoCalGas from California sources (state onshore plus state/federal offshore supplies) was about 300 MMcf/day in 1999. By late 2000, supplies from California sources are expected to increase due to additional deliveries from Elk Hills.

Southwestern U.S. Gas

Traditional Southwestern U.S. sources of natural gas, especially from the San Juan basin, will continue to supply most of southern California's natural gas demand. This gas is delivered via the El Paso Natural Gas Company and Transwestern Pipeline Company pipelines. The majority of San Juan basin gas is coalbed methane production, which has recently reached a plateau. Although the Unconventional Fuels Tax Credit (which expires in 2003) provides producers an incentive to produce as much gas as possible from wells drilled before 1993, coalbed methane drilling is still profitable in the San Juan Basin and parts of Utah and Wyoming. The San Juan Basin's conventionally produced gas supplies have increased since 1991 and are expected to help meet southern California's gas demand. Permian Basin gas will continue as the primary swing supply into California.

Rocky Mountain Gas

Rocky Mountain supply presents a viable alternative to traditional Southwestern U.S. gas sources for southern California. This gas is delivered to southern California primarily on the Kern River Gas Transmission Company's pipeline, although there is also access through the San Juan Basin. While the majority of Rocky Mountain gas is conventional gas supplies, substantial gas supplies also qualify for the Unconventional Fuels Tax Credit through year 2003 - mainly as tight formation gas and some as coal seam gas. In recent years, Rocky Mountain gas has increasingly flowed to Midwestern and Pacific Northwest markets.

GAS DEMAND (REQUIREMENTS)

OVERVIEW

SoCalGas expects continued growth in the residential market, along with associated service-oriented businesses in the commercial market. These markets, along with small industrial customers, comprise the core market. The remaining large customers make up the noncore market.

The following table compares the composition of SoCalGas' throughput for recorded year 1999 and forecast year 2020.

Composition of SoCalGas Throughput - Bcf (Average Temperature Year)			
	1999	2020	Change
Residential	278	311	12%
Core Non-residential	94	121	29%
Noncore C&I	164	164	0%
EOR-Steaming	9	7	-20%
Electric Generation	316	197	-38%
Wholesale	147	141	-4%
Other	19	19	0%
Total	1,025	960	-6%

NOTES:

"Core Non-residential" includes NGV throughput.

"Other" includes international (Mexicali) throughput and L&UAF+Company-Use gas.

Residential, core non-residential, and wholesale requirements are expected to increase as southern California's economy continues through a gradual economic expansion. Requirements for Enhanced Oil Recovery (EOR)-steaming operations, which have declined since the Kern/Mojave pipeline began offering direct service to California customers in 1992, are expected to continue to decline. The electric generation (EG) market is expected to decline dramatically as more electric power generation takes place outside SoCalGas' service territory. The decline in the wholesale demand is also explained by the electric power generation market impacts in SDG&E's service territory, more than offsetting and expected growth in other core and noncore wholesale markets.

MARKET SECTORS

Residential

Residential demand adjusted for temperature increased slightly to 253.4 Bcf in 1999 from 253.1 Bcf in 1998. Unadjusted residential demand was 277.6 Bcf in 1999, 10% more than temperature adjusted demand primarily because of colder than normal weather conditions in southern California.

Active residential meters averaged 4.73 million in 1999, an increase of 67,000 (or 1.4%) from the 1998 average. In 2000, SoCalGas expects an increase of more than 61,000 active meters. From 2000 through 2020, active residential meters are expected to grow at an average annual rate of 1.3%, reaching 6.18 million by 2020.

Residential demand is projected to grow from 253.1 Bcf in 2000 to 311.0 Bcf in 2020, an increase of 2.9 Bcf per year. SoCalGas' DSM programs are projected to save about 1 Bcf per year in the residential sector.

Commercial

On a temperature-adjusted basis, core commercial market demand in 1999 totaled 68.6 Bcf, up 2.4 Bcf from 1998. This increase is largely the result of continuing positive economic conditions in southern California. On average, core commercial market demand is forecast to increase about 1.1% per year, over the next 20 years, reaching 88.6 Bcf in 2020.

Noncore commercial demand in 1999 totaled 25.9 Bcf, a slight increase of 0.5 Bcf over 1998 usage. Noncore commercial demand is expected to grow at 0.4% per year, reaching 27.2 Bcf in 2020. This growth is primarily due to an expected increase in commercial employment.

Industrial

In 1999, temperature-adjusted core industrial demand was 19.1 Bcf, an increase of 0.8 Bcf over 1998 deliveries. However, retail core industrial market deliveries are projected to decline by approximately 0.2% per year over the forecast period, dropping to 17.8 Bcf in 2020. This decline results from a combination of a slightly lower industrial employment forecast, higher marginal gas rates and increases in gas equipment energy-efficiencies.

Retail industrial noncore deliveries are forecast to increase from 133.5 Bcf in 1999 to 138.0 Bcf in 2000, a net increase of 4.5 Bcf. Deliveries are forecast to further increase to 142.4 Bcf in 2002. The reason for this increase is the addition of new load in late 1999. After 2002, industrial noncore demand is forecast to decline gradually to 136.4 Bcf in 2020. This small decline is due to a combination of a declining industrial base and some customers switching to wholesale status.

Los Angeles, CA 90017

RE: Chatsworth Ridge Planning Environmental Documentation-Request for Electric Power Service

Dear Ms. Gillis:

The subject project currently has an existing overhead 16KV primary power line that feeds into the project site. This line feeds an existing pole top substation that serves an existing residential subdivision to the south with 4KV primary voltage. The 16KV line also feeds various areas throughout the proposed subdivision. This 16KV mainline will have adequate capacity to serve this proposed 500 unit single family residential subdivision.

It appears that we will need to replace or remove much of the existing overhead facilities on the property and replace it with a new underground system.

The developer will be responsible to provide all necessary trenching, backfill, conduits, and substructures at their expense. All necessary relocation or overhead to underground conversion costs will be also entirely at the developers expense.

If you have any further questions or concerns, please feel free to contact me at (805)494-7065 or email me at itoay@sce.com.

Sincerely,

Alan Y. Ito
Service Planner

Subject: Agency Comment (Negative Declaration) for Environmental Impact Report for "Chatsworth Ridge", City of Los Angeles County of Los Angeles, California (SCG Atlas # LA 1615, 1585)

Southern California
Gas Company
9200 Chatsworth Avenue
Chatsworth, CA
91311-2100
Mailing Address
Box 2500
Chatsworth, CA
91311-2500

This letter is not to be interpreted as a contractual commitment to serve this proposed project, but only as an information service. Its intent is to notify you that Southern California Gas Company has adequate supplies for the foreseeable future and facilities in the areas where this project is proposed. *A recent U.S. Department of Energy study reports that recoverable reserves and resources of natural gas in the lower 48 states total more than a 70-year supply at current production levels.* Gas service can be provided without significant impact on the environment, from a 6" medium pressure main in Topanga Canyon Blvd.

This proposal is within the S C Gas Utility Service Territory. S C Gas has designed the distribution pipeline system to meet the demand of total buildout in this area. Gas facilities will be extended into each project at the time of requirement. The pipeline extensions do not impact existing customers. We do not anticipate any cumulative infrastructure or gas provision inadequacies or short term construction related impacts. The gas mains and services are generally installed in joint trench with other dry utilities and, therefore, do not require any mitigation measures.

Encourage the energy engineer/architect to consult the Utility for an energy analysis regarding efficiency/conservation measures and up-to-date technology, manufacturing equipment, financial incentives, etc.

Service would be in accordance with our policies and extension rules on file with the California Public Utilities Commission at the time contractual arrangements are made. The availability of natural gas service, as set forth in this letter, is based on present conditions of gas supply and regulatory policies. As a public utility, Southern California Gas Company is under the jurisdiction of the California Public

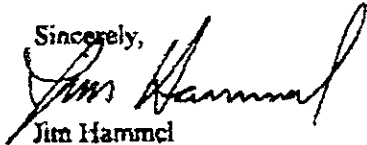

Jun-03-94 12:20P

P. 04

Utilities Commission. We can also be affected by actions of federal regulatory agencies. Should these agencies take any action which affects gas supply or the condition under which service is available, gas service will be provided in accordance with the revised conditions.

When any portion of the project has final approval by the city or county engineer, please contact Mr. Ron Reed, New Business Project Manager, at (818) 701-3476. It may require up to 90 days to process the application for the installation of gas lines in a particular project.

Sincerely,

Jim Hammett

Deerlake Ranch Mitigation Monitoring Program

1.0 INTRODUCTION

Pursuant to Section 21081.6 of the Public Resources Code and the *CEQA Guidelines* Section 15097, public agencies are required to adopt a monitoring or reporting program to assure that the mitigation measures and revisions identified in the EIR are implemented. As stated in Section 21081.6 of the Public Resources Code:

“... the public agency shall adopt a reporting or monitoring program for the changes to the project which it has adopted, or made a condition of project approval, in order to mitigate or avoid significant effects on the environment.”

Pursuant to Section 21081(a) of the Public Resources Code, findings must be adopted by the decision maker coincidental to certification of the EIR. The Mitigation Monitoring Program must be adopted when making the findings (at the time of approval of the project).

The public agency may delegate reporting or monitoring responsibilities to another public agency or a private entity, which accept the delegations. The lead agency, however, remains responsible for ensuring that implementation of the mitigation measures occur in accordance with the program.

As defined in the *CEQA Guidelines*, Section 15097, “reporting” is suited to projects that have readily measurable or quantitative measures or which already involve regular review. “Monitoring” is suited to projects with complex mitigation measures, such as wetland restoration or archaeological protection, which may exceed the expertise of the local agency to oversee, are expected to be implemented over a period of time, or require careful implementation to assure compliance. Both reporting and monitoring would be applicable to the Deerlake Ranch project.

2.0 MITIGATION MATRIX

In order to sufficiently track and document the status of mitigation measures, a mitigation matrix have been prepared and includes the following components:

- Mitigation measures
- Implementation responsibility
- Implementation date
- Monitor verification date
- Responsible agency
- Mitigation measure completion dates
- Comments

Mitigation measure implementation timing has been apportioned into ten specific timing increments, outlined as follows:

- Prior to issuance of Grading Permit
- Prior to issuance of Building Permit
- Prior to issuance of Certificate of Occupancy

Deerlake Ranch Mitigation Monitoring Program

Information pertaining to compliance with mitigation measures or any necessary modifications/refinements is documented in the comments portion of the matrix. The mitigation matrix follows this section.

3.0 MITIGATION MONITORING PROCEDURES

The Los Angeles County Department of Regional Planning is the designated lead agency for the Deerlake Ranch Mitigation Monitoring Program. The department is responsible for review of all monitoring reports, enforcement actions, and document disposition. The Department of Regional Planning will rely on information provided by the monitor as accurate and up to date and will field check mitigation measure status as required.

4.0 MONITORING REPORTS

Mitigation monitoring reports will be provided to the Los Angeles County Department of Regional Planning in conjunction with the timing milestones outlined in the Mitigation Monitoring Program. More frequent monitoring status reports can be provided, if required. Monitoring reports will document all of the mitigation components outlined in the matrix, and identify required modification or problems. The mitigation monitoring reports may at times refer to other more detailed monitoring documents prepared for the project. When this situation arises, these documents will be submitted along with the mitigation report for department review.

A pre-monitoring meeting will be scheduled with the applicant, Department of Regional Planning, and the monitor to review mitigation measures, implementation requirements, schedule conformance and reporting responsibilities.

Project monitors will exercise caution and professional practices at all times when monitoring construction mitigation measures. Protective wear (hard hat/glasses) will be worn at all times in construction areas. Injuries will be immediately reported to the mitigation monitor.

The construction manager/superintendent is responsible for coordination of contractors, and is responsible for contractor completion of required measures in accordance with the mitigation monitor.

The use of experts acceptable to the Department of Regional Planning, as a component of the monitoring team, is required to ensure compliance with scientific and engineering based mitigation measures. While recognized experts assesses compliance with the required mitigation measures, responsible agency staff will consult with the Department of Regional Planning regarding any disputes.

If the mitigation monitor identified an action, which, in the opinion of the monitor has not been implemented or has not been implemented correctly, the problem will be brought to the attention of the Department for resolution. If the problem cannot be satisfactorily resolved by Department staff, it will be brought before the Planning Director or designee for resolution. The arbitration committee, through the County Counsel, will have the authority to issue stop work orders until the dispute is resolved.

Agencies may enforce conditions of approval through their existing police power, using stop work orders, fines, infraction citations, loss of entitlement, refusal to issue building permits or certificates of use and occupancy, or in some cases notice of violation for tax purposes. Criminal misdemeanor sanctions could be available where the agency has adopted an ordinance requiring compliance with the monitoring program, similar to the provision in many zoning ordinances which state the enforcement power to bring suit against violators of the ordinance's provisions. Additional enforcement provisions included required posting of a bond or other acceptable security in the amount of the required mitigation measures.

<ul style="list-style-type: none"> • Permanent signs shall be installed along Canoga Avenue displaying "Watch for Equestrians", or similar language. 	APPLICANT	9		DPW		
<ul style="list-style-type: none"> • Signs shall be installed during the project construction period displaying "Jake Braking Strictly Prohibited," or similar language. 	APPLICANT	9		DPW		
<p>8. As agreed, the subdivider shall be responsible for repairing damage to the existing pavement on Canoga Avenue between Chatsworth Street and SR-118 that is caused by project contractors during the course of construction.</p>	APPLICANT	10		DPW		

Deerlake Ranch Mitigation Monitoring Program

Mitigation Monitoring Matrix Deerlake Ranch Final Program EIR SCH No. 200061049	Mitigation Monitoring Implementation Responsibility	Implementation Time Frame	Monitor Verification Date	Monitoring Responsible Party	Mitigation Measure Completed (Y/N)	Comments
Mitigation Measure						
9. The subdivider shall install three-way stop signs at the proposed intersection of Mayan Drive and "B" Street, subject to the approval of the County of Los Angeles.	APPLICANT	9		DPW		
10. The subdivider shall install all stop signs for equestrian crossings per the applicant's community commitments.	APPLICANT	9		DPW		
11. Caltrans has requested additional mitigation measures to mitigate impacts of the project within the State right-of-way. The applicant will prepare, as a voluntary measure, a Project Study Report (PSR) to address long-term regional traffic operations at the Topanga Canyon Boulevard/SR-118 interchange. In addition, the applicant shall consider possible payment of fair-share fees as determined by the County.	APPLICANT	9		DPW Caltrans		
UTILITIES & SERVICE SYSTEMS – WATER SUPPLY						
1. Water system distribution facilities shall meet the Las Virgenes Municipal Water District specifications and standards.	APPLICANT	2		LVMWD		
2. The project developer shall install low-flush toilets and low-flow showerheads, consistent with the LVMWD requirements.	APPLICANT	2		LVMWD		
3. The project shall comply with Water Conservation Ordinance Nos. 11-86-161 and 1-93-205.	APPLICANT	2		LVMWD		

Deerlake Ranch Mitigation Monitoring Program

Mitigation Monitoring Matrix Deerlake Ranch Final Program EIR SCH No. 200061049	Mitigation Monitoring Implementation Responsibility	Implementation Time Frame	Monitor Verification Date	Monitoring Responsible Party	Mitigation Measure Completed (Y/N)	Comments
Mitigation Measure						
4. Water conserving measures in landscape management shall include:						
<ul style="list-style-type: none"> • Use of drought-tolerant plantings. 	APPLICANT	5		LVMWD		
<ul style="list-style-type: none"> • Installation of efficient irrigation systems that minimize runoff and evaporation and maximize the water that will reach the plant roots. Setting of automatic irrigation systems to ensure irrigation during early morning or evening hours. Resetting of automatic irrigation system to water less often in cooler months and during the rainfall season so that water is not wasted by excessive landscape irrigation. 	APPLICANT	5		LVMWD		
UTILITIES & SERVICE SYSTEMS – WASTEWATER						
1. The project site shall be Annexed to LVMWD Sewer Improvement District "B".	APPLICANT	2		LVMWD		
2. Portions of the City of Los Angeles sewer system shall be constructed.	APPLICANT	2		LVMWD		
3. Low-flow toilets and showers shall be installed to minimize sewage generation from the proposed homes.	APPLICANT	2		LVMWD

<ul style="list-style-type: none"> Information on the proper disposal of hazardous materials. 	APPLICANT	10		LACSD		
UTILITIES & SERVICE SYSTEMS – ELECTRICITY						
1. Project built-in appliances, refrigerators, and space-conditioning equipment shall exceed the minimum efficiency levels mandated in the California Code of Regulations.	APPLICANT	8		SCE		
2. To reduce electricity consumption, fluorescent and high-intensity-discharge (HID) lamps shall be installed wherever possible, which give the highest light output per watt of electricity consumed, including all street lights consistent with the Los Angeles County of Public Works standards.	APPLICANT	2		SCE DPW		
UTILITIES & SERVICE SYSTEMS – NATURAL GAS						
1. Project buildings shall be designed and constructed to be well-sealed to prevent outside air from infiltrating and increasing interior space-conditioning loads.	APPLICANT	6		SCG		
2. Thermal insulation, which exceeds requirements established by the California Code of Regulations, shall be installed in walls and ceilings.	APPLICANT	6		SCG		

Mitigation Monitoring Matrix Deerlake Ranch Final Program EIR SCH No. 200061049	Mitigation Monitoring Implementation Responsibility	Implementation Time Frame	Monitor Verification Date	Monitoring Responsible Party	Mitigation Measure Completed (Y/N)	Comments
Mitigation Measure						
3. Window systems shall be designed to reduce thermal loss, thus reducing heating loads during cool weather.	APPLICANT	6		SCG		
4. Project energy engineers and architects shall consult with The Gas Company for an energy analysis of the proposed dwellings regarding efficiency/conservation measures and up-to-date technology, manufacturing equipment, etc.	APPLICANT	6		SCG		

Enclosure E

**ADDENDUM TO FINAL ENVIRONMENTAL IMPACT REPORT
FOR AMENDED VESTING TENTATIVE TRACT MAP NO. 53138
MODIFICATION OF CONDITIONAL USE PERMIT 99-239 (5) and
OAK TREE PERMIT ROAK #201200001**

1. Existing Entitlements

- a. On August 10, 2004, the County Board of Supervisors approved Vesting Tentative Tract Map (VTTM) No. 53138-(5), Conditional Use Permit (CUP) 99-239, Oak Tree Permit (OTP) 99-239, and certified the Final Environmental Impact Report (FEIR). The subject property is situated within the Chatsworth Zoned District of Los Angeles County, and is located north of the 118 Freeway, between Topanga Canyon Boulevard and Canoga Avenue. Subsequently, an Amended Vesting Tentative Tract Map was approved by the County Hearing Officer on September 16, 2008, authorizing certain design modifications.
- b. The approved VTTM and CUP authorizes the creation of 375 single-family residence lots, 21 open space lots, 14 private and future streets, four debris basins, one helispot, one sheriff's storefront facility, four designated remainder parcels on 230.58 acres, and project associated grading and infrastructure to be developed in compliance with hillside management and density controlled development design review criteria that allows clustering of the units into the least environmentally sensitive areas of the site while retaining the remaining portion of the property in permanent open space (See Sec. 2.0, Project Description of FEIR).
- c. The OTP authorized the removal of 61 oak trees, and encroachment into the protective zones of 11 oak trees. The OTP subsequently was revised on September 6, 2005, as OTP #200500037, and authorized the removal of 45 oak trees, and encroachment into the protective zones of 10 oak trees.
- d. Mitigation measures identified in the approved Final Environmental Impact report (FEIR) and Mitigation Monitoring Plan (MMP), and imposed on the project as a condition of approval, including the following categories: Aesthetics, Air Quality, Biological Resources, Cultural Resources, Geology, Hydrology, Noise, Fire Department Services, Police Services, Schools, Libraries, Traffic, Water Services, Wastewater Services, Solid Waste, Electric and Gas Services.

2. Proposed Entitlement Modifications

The proposed project modifications require the following amendments to, or new entitlements: Amended Map for Vesting Tentative Tract Map (VTTM) No. 53138, Modification to CUP 99-239, a new Oak Tree Permit (OTP) ROAK #201200001 and an Addendum to the approved FEIR.

3. Proposed Amended Vesting Tentative Tract Map No. 53138

- a. The Amended VTTM proposes to reduce the number of residential dwelling units from 375 to 314, with corresponding revisions on the map pertaining to lot and internal street configurations, related grading and infrastructure quantities, and lot numbers, consistent with the proposed Modification of the CUP, as described in this document.

- b. The Amended VTTM approved by the Hearing Officer permitted 20 designated lots to have less than 50 feet of frontage at the street right-of-way to accommodate lots located along street curves. Above 20 lots are in addition to the flag lots with 10' or 15' frontage per Section 21.24.320 and lots along cul-de-sac streets with 40' frontage per Section 21.24.300. This Amended VTTM proposes to modify the number of lots that would be permitted to have less than 50 ft. of frontage on the street from 20 to 31 and their designations from lot numbers 12 through 16, 29, 57 through 64, 365, and 370 through 374 to the following: Lot numbers 12, 13, 15 through 19, 33, 34, 37, 55, 63 through 69, 78, 92, 95 through 99, 101, 244, 296, 298, 299, 307, 310 and 311.
- c. In the southwesterly portion of the project, it is proposed to leave the ridgeline and a portion of the southerly slope of Devils Canyon in their natural states by reducing the area of the building envelope and the future street grading in the area (see Sec. 4.1, Aesthetic and Visual resources, of FEIR). This will result in a reduction of approximately 600,000 cubic yards (cy) of grading and related truck hauling to the northerly portion of the project, a reduction of approximately 110,000 sf of retaining wall, and a reduction the number of lots in that area from 48 to 23. To maximize preservation of the ridgeline, it is proposed to modify the road standard for a portion of Poema Place, between Topanga Canyon Blvd. and the westerly end of the proposed bridge Poema Place bridge, from "Collector Street" standards (40 ft. of paved roadway, and 55ft. of right-of- way) to "Private Driveway & Fire Lane" standards (36 ft. of paved roadway, and 42 ft. of roadway easement), as shown on the Amended VTTM. This proposed modification meets both Los Angeles County Fire Department and Department of Public Works standards.
- d. As result of the elimination of approximately 600,000 cy of fill material for the northerly portion of project, three out of the four main north-south drainage courses will be left in their natural state, except for road crossings, as shown on the Amended VTTM (see Sec. 4.3, Biological Resources, of FEIR). Because the three drainage courses will be kept in their natural state, three debris basins will be eliminated, as well as storm drain pipe, and inlet and outlet structures, that were to be constructed within those drainage courses. As a result, the number of lots in the northwesterly portion of the project has been reduced from 91 to 68.
- e. Portions of the internal street system of the north portion of project have been re-oriented, and modified from "Residential" standards (36 ft. paved roadway and 51 ft. right-of-way, and 34 ft. paved roadway and 49 ft. right-of way) to "Private Driveway & Fire Lane" standards (36 ft. paved roadway, 42 ft. of roadway easement and 34 ft paved roadway and 38 ft of roadway easement), as shown on the Amended VTTM. This proposed modification meets both Los Angeles County Fire Department and Department of Public Works standards. These modifications substantially reduce the size and area of required retaining walls in this area by approximately 73,000 sf. As a result, the number of lots in that area has been reduced from 136 to 120, and the lot frontages have been increased from a minimum 50 to 60 feet wide, to a minimum 60 to 70 feet wide.
- f. Configuration of the site plan and lot layout for the central portion of the project has been left essentially unchanged, except that the number of lots has been increased from 100 to 101.
- g. The requested Amendment to VTTM No. 53138 seeks authorization for the following modifications to the VTTM No. 53138 Conditions of Approval. All other Conditions of Approval shall remain in effect for this Amended VTTM.
 - Revise Condition #20 to read:

“Show Canoga Ave and Bullfinch Road, South of the proposed gates, Nogan Drive and Poema Place, from Canoga Ave to Cul-de-sac as dedicated streets on the final map.”

h. Revise Condition #21 to read:

“Show project access as Private Driveways and Fire Lanes on the final map.”

- Revise Condition #25 to read:

“Prior to recordation of any final unit map that includes Schindler Way, submit evidence satisfactory to the Director that an easement for ingress, egress, and underground utility purposes will be recorded for the benefit of properties to the north of the project. The easement shall extend by Lot 255 from the northerly tract boundary to Private Driveway and Fire Lane Schindler Way, continuing to a public road, all as shown on Vesting Tentative Tract Map No. 53138, and shall be a minimum of 28 feet, and a maximum of 58 feet in width.”

- Revise Condition #26 to read:

i. “Prior to recordation of any final unit map that includes Schindler Way, submit evidence satisfactory to the Director that an easement for ingress, egress, and underground utility purposes will be recorded for the benefit of properties to the north of the project, including those commonly referred to as the "Deerlake Addition." The easement shall extend by Lot 337 from the northerly tract boundary to Private Driveway and Fire Lane, Schindler Way, continuing to a public road, all as shown on Vesting Tentative Tract Map No. 53138, and shall be a minimum of 36 feet, and a maximum of 58 feet in width.”

- Revise Condition #27 to read:

“Prior to recordation of any final unit map that includes "X" Street, submit evidence satisfactory to the Director that an easement for ingress, egress and underground utility purposes will be recorded for the benefit of properties to the north of the project. The easement shall extend from the northerly property line of the project site at Lot 7 of Section 6, through and over "X" Street, across and within those portions of all Private Driveway and Fire Lanes which are northerly of the depicted gate entries on Tract Map No. 53138, to a public road, and shall be 64 feet in width, including slope easements. The easement shall terminate if and when the County of Los Angeles accepts the applicant's offer of dedication of "X" Street.”

- Revise Condition #28 to read:

“Grant to all persons holding title to land within the County of Los Angeles and the heirs, successors, and assigns of said persons, as their interest may now or hereafter appear of record, a non-exclusive easement for ingress and egress, road, and utility purposes over the private driveways and fire lanes in this subdivision to the satisfaction of the Department of Public Works and the Department of Regional Planning.”

- Revise Condition #29 to read:

“Permission is granted to use the alternate street cross section to the satisfaction of the Department of Regional Planning and Department of Public Works for all public streets”

- Revise Condition #30 as follows:
Revise Helispot lot number from #399 to #341
- Revise Condition #31 to read:
“Dedicate to the County of Los Angeles on the final map the right to prohibit the construction of residential and accessory structures over the lots designated as open space lots (Lots 315, 317-336, 338-340, 343, 344). Construction of recreational amenities is permitted subject to approval of plot plans by the Director of Planning. Recreational structures/facilities may be constructed on portions of lots 315, 324, 336, and 343 subject to approval of plot plans by the Director. Water and Sewer structures/facilities may be constructed on lots 327 and 342. Drainage structures/facilities may be constructed within open space lots as shown on the drainage concept/hydrology study approved by the Department of Public Works .
- Revise Condition #32 as follows:
Revise Sheriff’s Storefront Station lot number from #377 to #316
- Revise Condition #33 to read:
“Provide for the ownership and maintenance of the open space lots (Lots 315, 317 through 336, 338 through 340, 342 through 344) by the homeowners' association or dedicate the open space lots to a public agency to the satisfaction of the Department of Regional Planning.”
- Revise Condition #36 to read:
“Bond with the Department of Public Works for any recreational structures proposed for Lots 315 and 324 and the equestrian rest area within Lot 336.”

4. Proposed Modification of Conditional Use Permit & Revised Exhibit “A”

The requested Modification to CUP 99-239 (5), and Revised Exhibit “A”, seeks authorization for the following modifications to the CUP 99-239 Conditions of Approval. All other Conditions of Approval shall remain in effect for this CUP Modification.

- Revise Condition #1 to read:
“This grant authorizes the use of the subject property for a total of 314 single-family residential lots, one debris basin lot, one helispot lot, one sheriffs storefront facility lot, one sewer pump station lot, 25 open space lots, one "remainder parcels," and project-associated infrastructure to be developed in compliance with hillside management and density-controlled development design review criteria, as depicted on the Revised Exhibit A, (dated March 24, 2004) as amended on September 16, 2008, and February 21, 2012) subject to the following conditions of approval.”
- Revise Condition #2 to read:
“A minimum of 50 percent of the 314 lots, or 157 lots, shall be 15,000 square feet in size, or larger.”
- Revise Condition #16 to read:
The subject property shall be graded, developed and maintained in substantial compliance

with the approved Exhibit A, which includes the tentative tract map (dated March 24, 2004, revised February 21, 2012), Community Character booklet (revised December 2012), and exhibit maps. Amended or revised tentative maps approved for Vesting Tentative Tract Map No. 53138 may, at the discretion of the Director, constitute a revised Exhibit A.

- Re vise Condition #20 to read:
“Any future development of the lot designated as a remainder parcel shall be subject to the regulations in effect at the time of such development, including the provisions of sections 66410 et seq. of the California Government Code (Subdivision Map Act) and the requirements of the Subdivision and Zoning Ordinances.”
- Revise Conditions #22 to read:
“Two private active use areas shall be provided on open space lots 315 and 324 to the satisfaction of the Director. Amenities such as benches, playground equipment or other similar features shall be provided as depicted on the approved Exhibit A.”
- Revise Conditions #23 to read:
“A natural park area shall be provided on a portion of open space lot 343 as shown on the approved Exhibit A.”
- Revise Conditions #24 to read:
“An equestrian rest area shall be provided and permanently maintained by the Homeowners' Association on the parcel within lot 336, as depicted on the approved Exhibit A. If necessary, an alternative location in the same general vicinity may be considered subject to the approval of a revised Exhibit A.”
- Revise Conditions #25 to read:
“The permittee shall pay the Quimby in-lieu fee of \$ 342,720, as required by the Department of Parks and Recreation”
- Revise Conditions #56, 57 & 65:
Revise all references to “A Street” to read “Poema Place”
- Revise Conditions #64 to read:
“Pursuant to Chapter 22.72 of the County Code, pay a fee to the Los Angeles County Librarian prior to issuance of any building permit in the amount required by Chapter 22.72 at the time of payment and provide proof of payment to the Department of Regional Planning. The current fee amount is \$638 per dwelling unit (\$638 x 314 dwelling units = \$200,332). The permittee or its successor in interest may contact the County Librarian at (562) 940-8430 regarding payment of fees.”
- Revise Conditions #3 & #26:
Revise the number of equestrian lots that are specifically designated to accommodate horse keeping from 55 to 41. This requested reduction corresponds to the pro rata reduction in the number of lots that are suitable for equestrian use within the northwesterly portion of the project from 91 to 68 lots (i.e.,60 % of total lots are to be specifically designated to accommodate horse keeping). The revised conditions are to read as follows:

Condition #3: “A minimum of 41 lots shall be specifically designated to accommodate horse keeping”

Condition #26: “The area of individual lots shall substantially conform to that shown on

the approved Exhibit A and shall include at least 41 lots containing a minimum of 15,000 square feet and specifically designed to accommodate horse keeping. Each horse-keeping lot shall include a minimum area of 2,000 square feet designated specifically for horse keeping. No portion of the designated area shall be closer than 35 feet to any habitable structure and shall comply with the requirements of the County Code. Site plans depicting compliance shall be submitted to the Director prior to issuance of building permits.”

5. Summary of New Oak Tree Permit ROAK #201200001

- a. A new oak tree permit is required for this Amended VTTM because the limits of grading have been modified from the originally approved VTTM, as described in Paragraph 3, above, and as shown on the Amended VTTM and Revised Exhibit “A”.
- b. This new OTP authorizes the removal of 42 oak trees and encroachment into the protected zone of 13 oak trees, as shown in the Oak Tree Report by L. Newman Design Group, Inc., the consulting arborist, dated January 2012, and subject to all conditions stated in the report, and imposed by the County Forester.
- c. The applicant will not be required to mitigate for removal of trees unless they are of ordinance size upon removal. The project arborist shall notify the County Forester one week prior to scheduled removal so that final measurement of the tree can be made to determine the need to provide additional mitigation trees.
- d. Trenching, excavation or clearance of vegetation within the protected zone of an oak tree shall be accomplished by the use of hand tools or small hand-held power tools. Any major roots encountered shall be conserved to the extent possible and treated as recommended by the consulting arborist.”

6. CEQA Addendum Findings Pertaining to Project Modifications

CEQA Section 15164 authorizes a Lead Agency to prepare an Addendum to a previously certified Environmental Impact Report if changes or additions to the document are necessary, but none of the conditions described in Section 15162 are present, as described below:

- No substantial changes are proposed in the project which will require major revisions of the previous EIR due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects
- No substantial changes have occurred with respect to the circumstances under which the project is undertaken which will require major revisions of the previous EIR due to the involvement of new potentially significant environmental effects or a substantial increase the severity of previously identified potentially significant effects
- No new information of substantial importance, which was not known, and could not have been known with the exercise of reasonable diligence at the time the previous EIR was certified as complete, shows any of the following:
- The project will not have one or more significant effects not discussed in the previous EIR

- Potentially significant effects previously examined will not be substantially more severe than shown in the previous EIR
- No new mitigation measures or alternatives previously found to be infeasible have been found to be feasible but declined by the project proponent to be adopted
- No new mitigation measures or alternatives which are considerably different from those analyzed in the previous EIR, and that would substantially reduce one or more potentially significant effects on the environment, have been found and declined by the project proponent to be adopted

The EIR adopted by the Board of Supervisors on August 10, 2004, analyzed the following potential project impacts: Aesthetics, Air Quality, Biological Resources, Cultural Resources, Geology, Hydrology, Noise, Fire Department Services, Police Services, Schools, Libraries, Traffic, Water Services, Wastewater Services, Solid Waste, Electric and Gas Services. Impacts on all of these elements and/or services were found to be less than significant after appropriate mitigation, as identified in the approved FEIR and the Mitigation Monitoring Plan.

Following are comparisons between the originally approved project and the proposed modified project of the potential impacts identified in the FEIR:

COMPARISON OF IMPACTS

DESCRIPTION OF POTENTIAL IMPACTS	EXISTING 375-UNIT PROJECT	MODIFIED 314-UNIT PROJECT	DESCRIPTION OF MODIFICATIONS
Project Description (FEIR Sec. 2.0)	*375	*314	*Reduction of 61 residential units (16.3%)
Aesthetics & Visual Resources (FEIR Sec.4.1)	*71.4 ac. Open space	*90.7 ac. Open space	* Addition of 19.3 ac. natural area (8.4%) *Preservation of portion of ridgeline within southwesterly portion of site
Air Quality (FEIR Sec. 4.2)	*2,505,000 cy grading *375 units *375 units	*1,660,000 cy grading\ *314 units *314 units	* 33.7 % reduction in grading operation emissions * 16.3% reduction in building construction emissions * 16.3% reduction in long term vehicular emissions
Biological Resources (FEIR Sec. 4.3)	*71.4 ac. of open space *0.43 ac. of 404 permit impact	*90.7 ac. open space *0.22 ac. of 404 permit impact	*Addition of 19.3 ac. of natural area (8.4%) *_48.8_% less impact to US waters (404 Permit)
Oak Trees (FEIR Sec. 4.3)	* 45 oak trees removed *10 oak tree encroachments	* 42 oak trees removed *13 oak tree encroachments	*3 less oak tree removals *3 more encroachments
Cultural Resources (FEIR Sec. 4.4)	*71.4 ac open space	*90.7 ac. open space	* Addition of 19.3 ac. of natural area

Geology & Soils (FEIR Sec. 4.5)	*2,240,000 cy mass grading *265,000 cy remedial grading *269,000 sf retaining walls	*1,660,000 cy mass grading *0 cy remedial grading *86,000 sf retaining walls	*Reduction of 580,000 cy in mass grading (25.8%) *Reduction of 265,000 cy remedial grading (100%) *Reduction of 183,000 sf of retaining walls (68%)
Hydrology (FEIR Sec. 4.6)	*4 debris basins	*1 debris basin	*Reduction of 3 debris basins (75%)
Noise (FEIR Sec. 4.7)	*2,505,000 cy grading 375 units	*1,660,000 cy grading 314 units	*33.7% reduction in grading equipment impact *16.3% reduction of bldg. constr. equipment impact
Fire Protection Services (FEIR Sec. 4.8)	*375 units	*314 units	*16.3% reduction in residential structures to serve
DESCRIPTION OF POTENTIAL IMPACTS	EXISTING 375-UNIT PROJECT	MODIFIED 314-UNIT PROJECT	DESCRIPTION OF MODIFICATIONS
Police Protection Services (FEIR Sec. 4.9)	*375 units	*314 units	*16.3% reduction in residential houses to serve
Schools (FEIR Sec. 4.10)	*375 units	*314 units	*Approximate 16% reduction in student generation (one student per house, all classes)
Libraries (FEIR Sec. 4.11)	*375 units	*314 units	*16.3% reduction in library demand
Traffic (FEIR Sec. 4.12)	*375 units	*314 units	*Reduction of 610 vehicle trips per day (16.3%) after build-out
Potable Water (FEIR Sec. 4.13)	*375 units	*314 units	*Reduction of 20,880 gal. per day of demand (16.3%)
Wastewater (FEIR Sec.4.14)	*375 units	*314 units	*Reduction of 44,880 gal. day of sewage discharge (16.3%)
Solid Waste (FEIR Sec. 4.15)	*375 units	*314 units	*Reduction of 735 lbs./unit/day of solid waste per day (16.3%)
Electric and Gas (FEIR Sec. 4.16 & 4.17)	*375 units	*314 units	16.3 % reduction of demand for gas and electricity

The Modified Project proposes to implement the same mitigation measures as the previous project where the measures are not related to the number of units, although the potential impacts of the Modified Project will be less. Where mitigation measures are specifically related to the number of units, the Modified Project will implement the same mitigation measures, but on an appropriate pro rata basis.

As shown above, these project modifications will result in the reduction of each potential impact identified in the original FEIR, and, therefore, will not cross the thresholds identified in Section 15162 of the California Environmental Quality Act (CEQA) that would require a subsequent EIR.

Therefore, this Project Amendment qualifies for an Addendum to the previously approved EIR, as authorized under CEQA Section 15164.

1. INTRODUCTION

1.0 INTRODUCTION

SUMMARY

This is a Second Addendum to the Deerlake Ranch Final Environmental Impact Report (FEIR) (State Clearinghouse No. 2000061049, herein referred to as the “Addendum”), as certified by the Los Angeles County Board of Supervisors on August 10, 2004 (herein referred to as the “certified FEIR”), including the FEIR First Addendum certified by the Los Angeles County Planning Commission on July 18, 2012 (herein referred to as the “certified FEIR First Addendum”). This introduction describes the purpose of an addendum and provides a summary of the background of the planning and environmental review process conducted by Los Angeles County (“County”) for the Deerlake Ranch Project, including previously approved project modifications.

The following sections of the Addendum assess the potential environmental effects associated with modifications to the certified FEIR and the certified FEIR First Addendum in analysis of the proposed project modifications. All modifications in their entirety are herein referred to as the “Amended Project”. The proposed modifications of the Amended Project generally consist of the following:

- Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units; (refer to **Figure 3.0**, *Approved Vesting Tentative Tract Map 53138* and **Figure 4.0**, *Proposed Vesting Tentative Tract Map 53138*);
- Modification in the number of lots that would be permitted to have less than 50 feet of frontage on the street from 34 lots to 19 lots;
- Modification to portions of internal streets, including re-designation from “Residential” standards to “Private Driveway & Fire Lane” standards, as follows (refer to Figure 4.0):
 - Caymus Court (removed);
 - Swanson Way (slightly shortened); and
 - Wurster Way (slightly lengthened);
- Relocation of two previously approved entry gates southerly along Canoga Avenue and Bullfinch Road and re-designation from “Residential” standards to “Private Driveway & Fire Lane” of the additional sections behind the gates (refer to Figure. 3.0, Figure 4.0, and **Figure 6.0**, *Location Map of Proposed Amendments*);
- Adjustments to lot line configurations (refer to Figure 4.0);
- Elimination of six lots in a restricted use area, and related modifications to surrounding lots (refer to Figure 6.0);
- Elimination of the previously approved sewage pump station from the north side of Poema Way (refer to Figures 4.0 and 6.0);
- Increase multi-use trails from 18,810 to 22,755 linear feet (4.31 miles);

- Addition of a home owner's association (HOA) owned and maintained recreational facility on a site previously approved for four residential lots and a small cul-de-sac (refer to **Figure 7.0, Recreation Center Site Plan Comparison** and **Figure 8.0, Proposed Recreation Center Conceptual Plot Plan**);
- Amendments to the text of previously approved CUP Conditions to be consistent with the proposed Amended VTTM;
- Clarification of lot area to include both gross and net area per current County methodology; and
- Update of the final map phasing and a request to authorize recordation of a large lot parcel (Refer to Figure 4.0).

As analyzed in this Addendum, the Amended Project would not result in new significant environmental effects or a substantial increase in the quantity or nature of environmental effects previously identified in the certified FEIR and the certified FEIR First Addendum.

PURPOSE OF AN ADDENDUM

CEQA Section 15164 authorizes a Lead Agency to prepare an Addendum to a previously certified Environmental Impact Report if changes or additions to the document are necessary, but none of the conditions described in Section 15162 are present, as described below:

- No substantial changes are proposed in the project which will require major revisions of the previous EIR due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects;
- No substantial changes have occurred with respect to the circumstances under which the project is undertaken which will require major revisions of the previous EIR due to the involvement of new potentially significant environmental effects or a substantial increase the severity of previously identified potentially significant effects; and
- No new mitigation measures or alternatives which are considerably different from those analyzed in the previous EIR, and that would substantially reduce one or more potentially significant effects on the environment, have been found and declined by the project proponent to be adopted.

Public review of an Addendum is not required by CEQA. If new significant impacts or a substantial increase in the severity of significant impacts identified in the previous EIR would result, then preparation and circulation of a Subsequent or Supplemental EIR is required.

As discussed in this Addendum, the Amended Project does not constitute substantial changes to the project, nor is there any new information of substantial importance that requires the preparation of a Subsequent or Supplemental EIR. The analyses of the minor modifications of the Amended Project listed above, including the addition of a community recreation center, support the conclusion that modifications to the Deerlake Ranch Project will not result in any new significant impacts, or any substantial increase in the severity of the significant impacts identified in the certified FEIR and the certified FEIR First Addendum. In addition, no new information of substantial importance has been identified that indicates that the Amended Project would result in any new significant impacts or any substantial increase in the severity of the significant impacts identified in the certified FEIR and certified FEIR First Addendum.

This Addendum presents a comparison of the environmental impacts of the Amended Project with the impacts identified in the certified FEIR and certified FEIR First Addendum, followed by an analysis of the change in impacts due to the Amended Project, including the following environmental topics:

Aesthetics and Visual Resources, Air Quality, Biological Resources, Cultural Resources, Geology and Soils, Hydrology and Water Quality, Noise, Public Services - Fire Protection, Public Services - Police Protection, Public Services - Schools, Public Services - Libraries, Transportation/Traffic, Utilities and Service Systems - Water Supply, Utilities and Service Systems - Wastewater, Utilities and Service Systems - Solid Waste, Utilities and Service Systems - Electricity, and Utilities and Service Systems - Natural Gas. Impacts on all of these elements and/or services were found to be less than significant, after appropriate mitigation, in the certified FEIR.

BACKGROUND

Physical Features: The project site is located north of the 118 freeway between Canoga Avenue and Topanga Canyon Boulevard; refer to **Figure 1.0**, *Vicinity Map* and **Figure 2.0**, *Aerial Photograph*. The irregularly-shaped property is 230.58 gross acres in size with flat to hilly terrain. A large portion of the property is generally a plateau that is bordered to the west and south by Devil's Canyon and to the east by Browns Canyon.

Access: The project will take access from Canoga Avenue, a variable width dedicated public street, and Poema Place, a 64-foot wide dedicated public street, via Topanga Canyon Boulevard. Internal access will be provided by a 36-foot wide private driveways and fire lanes.

Services: Domestic water service will be provided by Las Virgenes Municipal Water District (LVMWD). Domestic sewer service will also be provided through the LVMWD via a contractual agreement with the City of Los Angeles. The project is within the boundaries of the Los Angeles Unified School District (LAUSD).

Land Use: A majority of the Project site is vacant. However, two single-family residences are included in Not A Part (NAP) areas surrounded by the project site, and one single-family residence is located along the easterly perimeter of the project site.

Zoning: The project site is currently zoned A-1-1 (Light Agricultural - One Acre Minimum Required Lot Area) and R-1-6,000 (Single-Family Residential - 6,000 Square Feet Minimum Required Lot Area).

History: The majority of the subject property was historically known as the Deerlake Highlands Tract, a Record of Survey subdivision of approximately 2,275 lots recorded in the late 1920's. Since their creation in the late 1920's, these substandard lots have occasionally been conveyed, sold, and acquired. These lots have been merged into 624 lots, each with a minimum of 6,000 square feet through the processing and issuing of 624 unconditional certificates of compliance.

VTTM No. 53138 was approved by the Los Angeles County Board of Supervisors on August 10, 2004, authorizing the creation of 375 single-family lots. Subsequently, additional modifications to the VTTM and CUP were approved, as described below.

PREVIOUSLY APPROVED PROJECT MODIFICATIONS

Tract Map 53138 was approved by the Los Angeles County Board of Supervisors on August 10, 2004 to authorize the creation of 375 single-family lots, 21 open space lots, 14 private and future street lots, four debris basin lots, one helispot lot, one sheriff's storefront facility, and four designated remainder parcels, on approximately 230.58 acres. Grading consisted of 2.2 million cubic yards of cut and fill. Additional approvals included CUP Case No. 99-239-(5), to authorize a density controlled residential development in a non-urban hillside management area; and Oak Tree Permit Case No. 99-239-(5) to permit the removal of 61 oak trees and encroachment into the protected zone of 11 oak trees.

Since the approval by the Board of Supervisors of VTTM 53138 and CUP 99-239 on August 10, 2004, the following modifications were subsequently approved:

Oak Tree Permit No. 200500037 was approved by the Los Angeles County Hearing Officer ("Hearing Officer") on September 6, 2005, to permit the removal of 47 oak trees and encroachment into the protected zones of ten oak trees, in addition to the removal of three dead oak trees. This permit superseded the original oak tree permit 99-239. Subsequently, Oak Tree Permit 201200001 was approved by the Planning Commission on July 18, 2012, for the reduction in the number of oak tree removals from 47 to 42, and maintain the same number of encroachments into the protected zone at 11.

Conditional Use Permit Modification No. 99-239 was approved by the Hearing Officer on September 19, 2006, to modify CUP condition no. 57 to allow the placement of construction trailers for the construction of "A" Street (Poema Place) bridge under specific conditions.

First Amendment to VTTM 53138 was approved by the Hearing Officer on September 16, 2008, to realign a portion of Canoga Avenue to accommodate a public trail realignment; revise phasing boundaries between Tentative Tract Map Nos. 53138-01 and 53138-03; revise phasing sequence number of unit maps; adjust lot lines; eliminate one of three sewer pump stations; depict final design of the two entry gates to be consistent with the conceptual designs of the Deerlake Ranch Community Character Statement; revise retaining walls in Neighborhood II; revise grading amount and grading footprint; eliminate all split-level building pads; and allow less than the required 50 feet of frontage for Lot Nos. 12 through 16, Lot No. 29, Lot Nos. 57 through 64, Lot No. 365, and Lot Nos. 370 through 374; construct a mainline sanitary sewer system for the adjoining Twin Lakes community to be accepted by the Los Angeles County Department of Public Works prior to the issuance of a building permit for the 190th home, and other minor changes.

Second Amendment to VTTM 53138 & CUP 201100160 was approved by the Planning Commission on July 18, 2012, and included the following (refer to Figure 3.0):

- Reduction in the number of single family lots from 375 to 314;
- Modification of road standards for Poema Place from a 55-foot wide collector street to a 36-foot wide private driveway and fire lane;
- Revised interior street standards from a 51-foot wide residential street to a 36-foot wide private driveway and fire lane;

- Reduction in the volume of project grading from 2.2 million cubic yards to 1.8 million cubic yards;
- Waiver of street frontage on lots fronting private driveways and fire lanes;
- Request to allow 34 lots to have less than the required street frontage;
- Reduction in the number of horse-keeping lots from 55 to 41;
- Reduction in the number of oak trees to be removed from 61 to 42 and increase in the number of encroachments from 11 to 13;
- Modification of the text of map approval conditions no. 10, 20, 21, 25, 26, 27, 28, 29, 30, 31, 32, 33, and 36 to reflect the amendments proposed by the amended tentative tract map
- Modification of Map Condition No. 38 pertaining to the construction, dedication, and placement of signage for the proposed Hiking and Equestrian Trails; and
- Modification of CUP Conditions No. 1, 2, 3, 16, 20, 22, 23, 24, 25, 26, 56, 57, 61, 64 and 65 to reflect the changes in number of lots, horse-keeping lots, types of lots, lot numbers, types of streets, street names and language for trails approved by the Second Amendment to VTTM 53138.

An application for a Third Amendment to the VTTM and Second Minor Modification to the CUP was filed on January 21, 2013, and consisted of a request to modify CUP Condition No. 69 to delete the construction of Twin Lakes Sewers and provide alternate benefit to the community; modify CUP Condition No. 65 to allow the construction of the Sheriff Station prior to the completion of A Street and Mayan Drive; and delete Department of Public Works Land Development Division Sewer Condition No. 8 related to Twin Lakes Sewers. This application was presented to the Subdivision Committee on May 2, 2013, but was subsequently retracted by the applicant.

2. PROJECT DESCRIPTION

2.0 PROJECT DESCRIPTION

AMENDED PROJECT

The proposed modifications of the Amended Project, Amended VTTM No. 53138 (“Fourth Amendment”), as shown in Figure 4.0, and Modification of the CUP (No. 201400166), will result in 314 residential units (similar to the certified FEIR First Addendum), 25 open space lots, one park, one debris basin lot, one helispot lot, one horse rest lot, one lot for a sheriff’s storefront facility, and one parcel for development of an HOA-controlled recreation center on a site previously approved for four residential lots and a cul-de-sac.

The Amended Project will also increase multi-use trails from 18,810 to 22,755 linear feet (4.31 miles) but there will be no changes to the conditions of approval pertaining to the trails.

In addition, the Amended Project will modify portions of interior streets previously approved to have 51-foot to 58-foot wide right of way, and a 34-foot to 36-foot wide paved roadway within that right-of-way, become private driveways and fire lanes with either a 42-foot wide right of way with a 36-foot wide paved roadway or a 38-foot wide right of way with a 34-foot wide paved roadway. Included with this street modification will be relocation of the two gates on Canoga Avenue and Bullfinch Road that were previously approved.

The Amended Project proposes minor reconfiguration of lots and adjustment of lot size, the reduction of the number of lots having less than 50 feet of frontage from 34 to 19, and would relocate six lots previously proposed within a geotechnical restricted use area (“RUA”) to other parts of the project site, thereby eliminating all lots within the RUA.

The approved Oak Tree Permit No. ROAK 201200001, authorizing the removal of 42 oak trees, and encroachment into the protective zones of 13 oak trees, will remain in effect, as there will be no changes to impacts on the existing oak trees on the project site.

PROPOSED MODIFICATIONS OF THE AMENDED PROJECT

The Amended VTTM 53138 (“Fourth Amendment”), and related minor modification of requested with CUP 201400166, proposes to make the following modifications to the Amended Project:

- Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units;
- Modification of the number of lots that would be permitted to have less than 50 feet of frontage on the street from 34 to 19 (refer to Figure 4.0);
- Portions of the internal street system will be modified from “Residential” standards (36-foot paved roadway within 51-foot right-of-way, and 34-foot paved roadway within 49-foot right-of-way) to “Private Driveway & Fire Lane” standards (36-foot paved roadway within 42-foot of roadway easement and 34-foot paved roadway within 38-foot of roadway easement), as shown on the Amended VTTM (refer to Figure 4.0).
- These modifications of street designations and widths were previously approved by the Planning Commission, and the proposed modifications merely change the extent and locations of those

previously approved, including the corresponding relocation of the two gates. The modifications meet both Los Angeles County Fire Department and Department of Public Works standards. The streets affected are:

- Caymus Court (removed);
 - Swanson Way (slightly shortened); and
 - Wurster Way (slightly lengthened).
- Relocation of two previously approved entry gates southerly along Canoga Avenue and Bullfinch Road and re-designation from “Residential” standards to “Private Driveway & Fire Lane” of the additional sections behind the gates (Refer to Figure 4.0 and Figure 6.0);
 - The construction, dedication, and signage of the approved Hiking and Equestrian trail system, including approved Map Condition No. 38 will remain unchanged, and dedicated to the satisfaction of the Department of Parks and Recreation, although the actual trail alignments are modified (refer to **Figure 5.0, Trails Overlay**);
 - Increase multi-use trails from 18,810 to 22,755 linear feet (4.31 miles);
 - Elimination of six lots in a geological RUA in the southwesterly portion of the project along the southerly slope of Devils Canyon, and related lot line adjustments to surrounding lots (refer to Figure 3.0 and Figure 5.0);
 - Elimination of the previously approved sewage pump station from the north side of Poema Way (refer to Figure 4.0 and Figure 6.0);
 - Addition of a private recreation center, consistent with section 22.20.100 of the Los Angeles County Code and proposed modification of the CUP, on a site previously approved for four residential lots and a short cul-de-sac (Rausch Court) (refer to Figure 7.0 and Figure 8.0);
 - Update in final map phasing, including construction of the Sheriff’s Storefront Facility and the Poema Bridge at an earlier phase (refer to Figure 4.0);
 - Clarification of lot area to include both gross and net area per current County methodology;
 - Request to recordation of a large lot parcel map for finance purposes (refer to Figure 4.0); and
 - Modification of appropriate sections of the Community Character Book, including the addition of architectural styles.
 - The requested Fourth Amendment to VTTM No. 53138 seeks authorization for the following modifications to the VTTM No. 53138 (Second Amendment) Tract Conditions of Approval. All other Conditions of Approval shall remain in effect for this Amended VTTM.
 - Condition No. 6, as currently approved, reads as follows: Submit evidence that the conditions of the associated Conditional Use Permit Case No. 99-239-(5) and Oak Tree Permit Case No. 99-239-(5) have been recorded.
 - With the requested fourth amendment to the VTTM, the applicant would modify the condition to read as follows: Submit evidence that the conditions of Conditional Use Permit 99-239-(5), Conditional Use Permit Modification No. 201100160, Conditional Use Permit Modification 201400166 and Oak Tree Permit Case No. 201300001 have been recorded.

- Condition No. 10, as currently approved, reads as follows: Provide at least 40 feet of frontage at the property line for each lot fronting on a cul-de-sac and knuckle, and at least 50 feet of frontage at the property line for all other lots, except for Lot Nos. 12, 13, 15, 16, 17, 18, 19, 33, 34, 37, 55, 63, 64, 65, 66, 67, 68, 69, 78, 92, 95, 96, 97, 98, 99, 101, 157, 244, 296, 298, 299, 307, 310, 311, which may have the reduced frontage indicated on the Amended Vesting Tentative Tract Map dated July 12, 2011, and except for flag lots. Provide approximately radial lot lines for each lot.

With the requested fourth amendment to the VTTM, the applicant would modify the condition to read as follows: Provide at least 40 feet of frontage at the property line for each lot fronting on a cul-de-sac and knuckle, and at least 50 feet of frontage at the property line for all other lots except for Lots No. 1, 2, 3, 6, 7, 8, 13, 14, 15, 49, 51, 52, 67, 68, 97, 98, 99, 100, and 101, which may have the reduced frontage indicated on the Amended Vesting Tentative Tract Map dated July 22, 2015, and except for flag lots, lots numbered 50, 53, and 54. Provide approximately radial lot lines for each lot.

- Conditions No. 25 (Lot 255), 30 (Lot 390), 31 (Lots 315, 317-336, 338-340, 343, 344), 33 (Lots 315, 317 through 336, and 338 through 340, 333 and 334), and 36 (Lots 315, 324, and 336), as currently approved, place certain conditions on the project that refer to specific lot numbers on the map of VTTM 53138 (Second Amendment).

With the requested fourth amendment to the VTTM, the applicant would modify these conditions only to revise the respective lot numbers referenced in these conditions in order to be consistent with the amended VTTM (Fourth Amendment). The following changes are proposed: Conditions No. 25 (Lot 283), 30 (Lot 341), 31 (Lots 315-345), 33 (Lots 317 through 335, and 338 through 340, 342-343 and 345), and 36 (Lots 315, 336, and 344). The content and meaning of each of these conditions remain unchanged.

- Condition No. 45, as currently approved reads as follows: Permission is granted to record multiple final maps. The boundaries of the final unit maps shall be to the satisfaction of the Department of Public Works and the Department of Regional Planning. Each unit final map to record shall comply on its own, or in combination with previously recorded final unit maps, with the open space and lot area requirements of the General Plan, the Zoning Ordinance, and Conditional Use Permit 99-239-(5). Prior to approval of each unit final map, submit the following:
 - A phasing map indicating the boundaries of the current final map, the boundaries and status of all previously filed final unit maps and the expected boundaries and phasing of all future final maps; and
 - A summary sheet indicating the number and type of all lots shown on the current and previous final maps.

With the requested fourth amendment to the VTTM, the applicant would modify the condition to read as follows: Permission is granted to record multiple final maps. The boundaries of the final unit maps shall be to the satisfaction of the Department of Public Works and the Department of Regional Planning. Each unit final map to record shall comply on its own, or in combination with previously recorded final unit maps, with the open space and lot area requirements of the General Plan, the Zoning Ordinance, and Conditional Use Permit 99-239-(5), Conditional Use Permit Modification No.2011000160 and Conditional Use Permit Modification 201400166. Prior to approval of each unit final map, submit the following:

- A phasing map indicating the boundaries of the current final map, the boundaries and status of all previously filed final unit maps and the expected boundaries and phasing of all future final maps; and
- A summary sheet indicating the number and type of all lots shown on the current and previous final maps.

In addition, a new condition granting permission to record a large lot parcel map will be added.

The requested Modification CUP No. 201400166, and Revised Exhibit "A", seeks authorization for the following modifications to the CUP No. 201100160 Conditions of Approval. All other Conditions of Approval shall remain in effect for this CUP Modification.

- Condition No. 1, as currently approved, reads as follows: The grant authorizes the use of the subject property for a total of 314 single-family residential lots, one debris basin lot, one helispot lot, one sheriffs storefront facility, 25 open space lots, one "remainder parcel," and project-associated infrastructure to be developed in compliance with hillside management and density-controlled development design review criteria, as depicted on the approved Exhibit "A" (dated March 24, 2004), as amended on September 16, 2008, and July 18, 2012, subject to the following conditions of approval.

With the requested modification, the applicant is revising and adding the following to Condition No. 1 and it would read as follows: The grant authorizes the use of the subject property for a total of 314 single-family residential lots, one debris basin lot, one helispot lot, one sheriffs storefront facility, a private recreation center, 25 open space lots, one park, one horse rest lot, and project-associated infrastructure to be developed in compliance with hillside management and density-controlled development design review criteria, as depicted on the approved Exhibit "A" (dated July 22, 2015), subject to the following conditions of approval.

- Condition No. 2, as currently approved, reads as follows: A minimum of 50 percent of the 314 lots, or 157 lots, shall be 15,000 square feet.

With the requested modification, the applicant is revising and adding the following to Condition No. 2 and it would read as follows: A minimum of 50 percent of the 314 lots, or 157 lots, shall have a gross area of at least 15,000 square feet. A minimum of 136 lots shall contain a minimum net area of 15,000 square feet.

- Condition No. 16, as currently approved, reads as follows: The subject property shall be graded, developed and maintained in substantial compliance with the approved Exhibit "A", which includes the amended vesting tentative tract map (dated March 10, 2011), Community Character booklet, and exhibit maps. Amended or revised tentative maps approved for Vesting Tentative Tract Map No. 53138 may, at the discretion of the Director, constitute a revised Exhibit "A".

With the requested modification, the applicant is revising and adding the following to Condition No. 16 and it would read as follows: The subject property shall be graded, developed and maintained in substantial compliance with the approved Exhibit "A", which includes the amended vesting tentative tract map (dated July 12, 2015), Community Character booklet, and

exhibit map. Amended or revised tentative maps approved for Vesting Tentative Tract Map No. 53138 may, at the discretion of the Director, constitute a revised Exhibit "A".

- Condition No. 20, as currently approved, reads as follows: Any future development of the one lot designated as a remainder parcel shall be subject to the regulations in effect at the time of such development, including the provisions of Section 66410 *et seq.* of the California Government Code (Subdivision Map Act) and the requirements of the Subdivision and Zoning Ordinances.

With the requested modification, the applicant is revising and adding the following to Condition No. 20 and it would read as follows: Any future development of the Not-A-Part parcels shall be subject to the regulations in effect at the time of such development, including the provisions of Section 66410 *et seq.* of the California Government Code (Subdivision Map Act) and the requirements of the Subdivision and Zoning Ordinances. The project has been designed to allow the flexibility to integrate these parcels into the project design.

- Condition No. 21, as currently approved, reads as follows: The applicant shall provide no less than 175 acres of open space, representing 76 percent of the project site, consisting of 73.5 acres of undeveloped area, 58.7 acres of landscaped slopes, and 4.69 acres of riding and hiking trails and 39 acres of landscaped yards. An additional 68 acres off-site shall be dedicated to the County or public conservation agency satisfactory to the Director, as biological mitigation pursuant to the Mitigation Monitoring Plan and Environmental Findings of Fact for the project.

With the requested modification, the applicant is revising and adding the following to Condition No. 21 and it would read as follows: The applicant shall provide 182.45 acres of open space, representing 79 percent of the project site as depicted on the Open Space Exhibit (2015), consisting of undeveloped area, riding and hiking trails, graded slopes and open space within private lots, a park, a horse rest area, a recreation center and other recreational amenities. Proof of dedication of 68 acres off-site as biological mitigation pursuant to the Mitigation Monitoring Plan and Environmental Findings of Fact shall be submitted.

- Condition No. 24, as currently approved, reads as follows: An equestrian rest area shall be provided and permanently maintained by the Homeowners' Association on the parcel adjacent to Lot 336, as depicted on the approved Exhibit "A". If necessary, an alternative location in the same general vicinity may be considered subject to the approval of a revised Exhibit "A".

With the requested modification, the applicant is revising and adding the following to Condition No. 24 and it would read as follows: An equestrian rest area shall be provided and permanently maintained by the Homeowners' Association on Lot 336, as depicted on the approved Exhibit "A".

- Condition No. 64, as currently approved, reads as follows: Pursuant to Chapter 22.72 of the County Code, pay a fee to the Los Angeles County Librarian prior to issuance of any building permit in the amount required by Chapter 22.72 at the time of payment and provide proof of payment to the Department of Regional Planning. The current fee amount is \$829 per dwelling unit (\$829 X 314 dwelling units = \$260,306). The permittee or its successor in interest may contact the County Librarian at (562) 940-8430.

With the requested modification, the applicant is revising and adding the following to Condition No. 64 and it would read as follows: Pursuant to Chapter 22.72 of the County Code, pay a fee to the Los Angeles County Librarian prior to issuance of any building permit in the amount required by Chapter 22.72 at the time of payment and provide proof of payment to the

Department of Regional Planning. The current fee amount is \$869 per dwelling unit (\$869 x 314 dwelling units = \$272,866). The permittee or its successor in interest may contact the County Librarian at (562) 940-8430.

- Condition No. 73, as currently approved, reads as follows: As required by the project mitigation measures and the conditions of Vesting Tentative Tract Map No, 53138, the permittee shall comply with the traffic improvement conditions set forth in the letter, dated July 28, 2003 from the City of Los Angeles Department of Transportation as its attached letter dated June 6, 2002, from the City of Los Angeles Department of Transportation. All transportation improvements shall be subject to the issuance of all required permits by the agencies with appropriate jurisdiction, including Los Angeles County Department of Public Works, Los Angeles City Department of Transportation ("LADOT") and the California Department of Transportation ("CALTRANS").

With the requested modification, the applicant is revising and adding the following to Condition No. 73 and it would read as follows: As required by the project mitigation measures and the conditions of Vesting Tentative Tract Map No, 53138, the permittee shall comply with the traffic improvement conditions set forth in the amended letter, dated March 6, 2006 from the City of Los Angeles Department of Transportation. All transportation improvements shall be subject to the issuance of all required permits by the agencies with appropriate jurisdiction, including Los Angeles County Department of Public Works, Los Angeles City Department of Transportation ("LADOT") and the California Department of Transportation ("CALTRANS").

The proposed modifications also include the development of an HOA-controlled recreation center on the site, as shown on the amended VTTM and the Revised Exhibit "A" of the CUP modification.

Under Section 22.20.100 of the Los Angeles County Zoning Ordinance, the following may be permitted within an R-1 zone, subject to a conditional use permit: *"Recreation facilities, neighborhood, not accessory to a principal use, including tennis, polo and swimming, where operated as a nonprofit corporation for the use of the surrounding residents. This provision shall not be interpreted to permit commercial enterprises"*. The proposed modification of the approved CUP includes the request for the recreation facility, consistent with the above-referenced Zoning Ordinance Section 22.20.100.

The recreation center will be located on a site previously approved for four single family residential lots and a short cul-de-sac street to serve these lots. The building pad of the recreation center site will coincide with the combined building pads and cul-de-sac sites (refer to Figure 7.0 and Figure 8.0).

The recreation center building setbacks from lot lines will be similar to those required for single family homes. Therefore, both on-site and off-site visual impacts will be similar to those that would have existed for the four residential homes (refer to Figure 4.0 and Figure 6.0).

The proposed recreation center will be owned, operated and maintained by the Deerlake Ranch Homeowners Association, and will serve only the residents within Deerlake Ranch community. The facility would be open daily with hours established to limit potential impacts on the surrounding area. Generally, the recreation center would be open no earlier than 7 A.M. and close at 10 P.M., in compliance with the County Noise Ordinance and project covenants, conditions, and restrictions (CC&R's), which will be reviewed by the County Planning Department, as required by Condition No. 32 of the approved CUP.

Table 2.0-1

Summary Of Project Modifications

Description of Items Previously Approved or Being Proposed	Applicable to Certified FEIR First Addendum	Applicable to Amended Project	Comments
No. of Residential Lots	314	314	No change
On-Site Recreation Facility	No	Yes	See text for further discussion
No. of Lots with less than 50 feet of frontage	34	19	44% reduction
No. of Lots within a Restricted Use Area	6	0	100% reduction
Area of Open Space Lots	84.07 acres	84.84 acres	1% increase
Modified internal street sections From "Residential" to "Private Driveway & Fire Lane"	Yes	Yes	Minor revisions in lengths & location of modified street sections previously approved
One gate each at Canoga Avenue and Bullfinch Road approved by Public Works & Fire Dept.	Yes	Yes	Gates re-located southerly along respective streets to private more lots behind gates. No change in street alignments or grades.
Public Hiking and Equestrian Trail System	Yes	Yes	No change in construction, dedication to County, or signage requirements of approved project conditions; trail alignments are increased by 3,945 feet
Amendments to text of certain previously approved CUP Conditions to be consistent with the proposed Amended VTT Map	Yes	Yes	Modifications in text are for consistency with Amended VTT Map only and do not reflect actual project modifications
Minor Lot Line Adjustments	Yes	Yes	No substantial effect on project grading or street system
Modification of Project Phasing	Yes	Yes	Construction of Sheriff's Storefront and Poema Bridge in earlier phase

Source: PCR Services Corporation, 2015

The proposed recreation center is planned to contain a pool, wading area, spa, restrooms, recreation building, tot lot, barbeque area and parking lot. When completed, the recreation center will be deeded to the Deerlake Ranch Homeowners Association.

The architectural design of the recreational facility buildings will be consistent with the Revised Community Character Booklet, which is included as part of this proposed CUP modification.

The construction, dedication, and signage of the approved Hiking and Equestrian trail system, including approved vesting tentative tract map Condition No. 38 will remain unchanged, and dedicated to the satisfaction of the Department of Parks and Recreation, although the actual trail alignments are modified (refer to Figure. 5.0). The amended multi-use trail alignments will increase from 18,810 to 22,755 linear feet (4.31 miles).

The Amended Project proposes a slight increase of open space, and reduces the number of lots with less than 50 feet of frontage than the previously Approved Project analyzed in the certified FEIR First Addendum. As such, the street design, basic circulation, and grading will remain essentially the same as described in the certified FEIR First Addendum. Therefore, the appropriate mechanism for processing and approving the Amended Project is through an Amended VTTM, in accordance with County Planning Department policies.

In addition, the Amended Project will not result in a substantial alteration or material deviation from the terms and conditions of the previously approved conditional use permit, and is necessary to allow the reasonable operation and use previously granted. Therefore, the appropriate mechanism for processing and approving the Amended Project is through a minor modification of the CUP in accordance with Section 22.56.1600 of the County Zoning Code.

3. IMPACT ANALYSIS

3.0 IMPACT ANALYSIS

SUMMARY

This analysis section includes separate subsections for each environmental topic addressed in the Deerlake Ranch FEIR certified by the Los Angeles County Board of Supervisors on August 10, 2004 (the “certified FEIR”) and subsequent FEIR First Addendum certified by the Los Angeles County Planning Commission on July 18, 2012 (the “certified FEIR First Addendum”). Each topical section first presents a summary of the information and conclusions of the analysis in the certified FEIR. For each topic a determination is also made whether the proposed modifications of the Amended Project would result in any new significant impacts or any substantial increase in the severity of the impacts identified in the certified FEIR and the certified FEIR First Addendum. Impact analysis topics in this section are presented in the same order as in the certified FEIR.

The certified FEIR analyzed the following potential project impacts: Aesthetics and Visual Resources, Air Quality, Biological Resources, Cultural Resources, Geology and Soils, Hydrology and Water Quality, Noise, Public Services - Fire Protection, Public Services - Police Protection, Public Services - Schools, Public Services - Libraries, Transportation/Traffic, Utilities and Service Systems - Water Supply, Utilities and Service Systems - Wastewater, Utilities and Service Systems - Solid Waste, Utilities and Service Systems - Electricity and Utilities and Service Systems – Natural Gas. Impacts on all of these elements and/or services were found to be less than significant after appropriate mitigation, as identified in the certified FEIR and the Mitigation Monitoring Plan (“MMP”). Subsequently, the County Planning Commission, as analyzed in the certified FEIR First Addendum, found that impacts due to the Second Amended Map on all of the above-described elements and/or services were found to be less than significant with the mitigation identified in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.1 - AESTHETIC AND VISUAL RESOURCES

Summary of Analysis in Certified FEIR

The certified FEIR states that implementation of the proposed project would result in a significant impact upon aesthetics and visual resources, as defined in *State CEQA Guidelines*, if any of the following occurs:

- The project would have a substantial adverse effect on a scenic vista;
- Project development would substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway;
- The project would substantially degrade the existing visual character or quality of the site and its surroundings; and/or
- Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area.

Additionally, more detailed criteria to determine whether or not a project’s changes in the existing landscape could be considered significantly adverse are provided in the County’s *Environmental Document Reporting and Procedures Guidelines*. If a project meets one or more of the listed criteria to a substantial degree, it can

be concluded that the project could result in a significant visual impact. The County criteria include consideration of the following:

- Is the project adjacent to a visual corridor? (And would the project substantially affect a visual corridor?)
- Does the project obstruct unique views from other developments or vantage points?
- Is the project out of character in an area with unique aesthetic features?
- Does the scale (height, bulk) of the project exceed that existing in the surrounding area? (This criterion usually applies within already urbanized areas)?
- Does the Project result in sun/shadow effects on adjacent land uses?

The certified FEIR concludes that implementation of the proposed project would not exceed any of the identified *State CEQA Guidelines* or *Los Angeles County Environmental Document Reporting and Procedures Guidelines* which are the criteria which establish a significant aesthetic impact. The project will not introduce elements which will substantially detract from the existing aesthetic character or primary aesthetic resources of the area. The height and bulk of structural elements proposed by the project would be compatible, and create a visual relationship, with existing development in the project vicinity. The project would not obstruct views from County designated scenic highways.

Although significant impacts to aesthetic and/or visual resources would not result with implementation of the project, the following mitigation measures are proposed to further reduce insignificant impacts:

- 4.1-1. The primary east-west ridgeline along the northern project boundary shall be retained in undisturbed natural open space to provide for a natural viewshed backdrop;
- 4.1-2. Approximately 70 acres of the project site has been or is proposed to be dedicated to the Santa Monica Mountains Conservancy for preservation of significant aesthetic resources. Those portions not currently dedicated as undisturbed open space shall be dedicated prior to issuance of a grading or building permit, whichever occurs first; and
- 4.1-3. A comprehensive landscape plan shall be approved by the County, prior to the issuance of a grading permit or building permit, whichever occurs first.

No unavoidable significant impacts with regard to aesthetics and visual resources would result with the implementation of the project, as concluded in the certified FEIR.

Analysis of the Amended Project

Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units, a reduction of 61 residential units from the certified FEIR (375 residential units), which reduces the overall impacts upon aesthetics and visual resources. Further, the Amended Project proposes 84.8 acres of open space lots, an increase of 13.4 acres of open space from the certified FEIR (71.4 acres) and an increase of 0.7 acres of open space from the certified FEIR First Addendum (84.1 acres). Lastly, the certified FEIR First Addendum proposed a reduction in grading quantities from the certified FEIR (2.2 million cubic yards) to 1.8 million cubic yards. All grading limits and building envelopes of the Amended Project will remain the same

as those of the certified FEIR First Addendum, including leaving portions of four drainage courses in their natural state (refer to Figure 4.0).

The Amended Project proposes a recreation center to be located on a site previously approved for four single family residential lots and a short cul-de-sac street serving these lots. The building pad of the recreation center site will coincide with the combined building pads and cul-de-sac (refer to Figure 7.0).

The building setbacks will be similar to those required for the single family homes. Therefore, both on-site and off-site visual impacts will be similar to those that would have existed for the four residential homes (refer to Figure 7.0). In addition, the architectural design of the recreational facility buildings will be consistent with the approved Community Character Booklet.

As such, the proposed modifications of the Amended Project, including addition of the recreation center, will not be substantially different from the project analyzed in the certified FEIR First Addendum and the same mitigation measures (4.1-1 through 4.1-3) will be implemented as for the certified FEIR. Therefore, no new or substantially greater visual impacts beyond those previously identified in the certified FEIR and certified FEIR First Addendum would occur as a result of the Amended Project.

CERTIFIED FEIR SECTION 4.2 - AIR QUALITY

Summary of Analysis in Certified FEIR

The certified FEIR states that: construction and operation of the proposed project would generate pollutant emissions from the following activities: (1) grading operations/soil disturbance; (2) emissions from construction activity and vehicular trips; (3) fugitive dust emissions from construction activity; (4) erosion “spill-over” from construction activity; (5) application of architectural surface treatments; and (6) vehicular exhaust (traffic) from project operation.

Temporary grading and construction emissions would occur during project buildout and include on-site generation of dust and equipment exhaust, and off-site emissions from construction vehicular traffic.

Air pollution emissions associated with project occupancy and operation would be generated by the operation of motor vehicles traveling throughout Southern California. Secondary impact potential would be derived from energy consumption in power plants or on-site heaters, stoves, water heaters, etc.

The certified FEIR recommends several mitigation measures (4.2-1 through 4.2-3) to reduce air quality impacts associated with construction activities to less than significant (see Section 4.2.2 of the certified FEIR for a complete list of mitigation measures).

The certified FEIR further states that although all mobile source emissions are predicted to be at or below SCAQMD significance thresholds, the following mitigation is recommended:

- 4.2-4. Homes shall be built to meet minimum statewide energy conservation requirements.

- 4.2-5. Homes shall include as an option the following residential design features that encourage trip elimination or trip diversion to alternative transportation:
- Pre-wired for various telecommunications systems access for in-home offices
 - Pre-wired for 220V electric vehicle charging systems

The certified FEIR concludes that the proposed project would contribute to the continued regional air quality degradation by exceeding SCAQMD significance thresholds as construction activity related emissions would exceed significance thresholds. With incorporation of the recommended mitigation measures, short-term construction activity impacts would remain significant, but the number of days that thresholds would be exceeded would be reduced. Operational impacts would not be significant; however, mitigation measures are recommended due to the non-attainment status of the (South Coast Air) Basin.

Analysis of the Amended Project

Since certification of the FEIR by the Board of Supervisors on August 10, 2004, which approved 375 residential units, the Planning Commission approved on July 18, 2012 the reduction to 314 residential units and reduced grading quantities from 2.2 million cubic yards to 1.8 million cubic yards without any corresponding reduction in the mitigation measures previously approved, as discussed in the certified FEIR First Addendum. As such, the mitigation measures (4.2-1 through 4.2-5) originally approved exceed those that would have been required for the certified FEIR First Addendum project.

The Amended Project proposes a substantially reduced amount of grading and infrastructure work as analyzed in the certified FEIR and similar to the discussion in the certified FEIR First Addendum. As such, the same mitigation measures will be implemented as stated in the certified FEIR. Therefore, no new or substantially greater temporary air quality impacts beyond those previously identified in the certified FEIR and certified FEIR First Addendum would occur as a result of the Amended Project.

Along with the reduction in the number of residential units from 375 (certified FEIR) to 314 (certified FEIR First Addendum and the Amended Project), the Amended Project proposes the addition of an on-site recreation center. The addition of an on-site recreation center for use by the project residents will reduce the number of vehicle trips by residents who would seek similar recreational opportunities off-site in the absence of an on-site facility. Additional off-site vehicle trips generated by the recreation center personnel are anticipated to be minimal.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase operational air quality impacts from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and the MMP.

CERTIFIED FEIR SECTION 4.3 - BIOLOGICAL RESOURCES

Summary of Analysis in Certified FEIR

The certified FEIR states that the Deerlake Ranch project would result in direct impact on the initial loss of habitats by grading and construction, and indirect impact related to disturbance from construction, such as

dust and noise, or from activities of future residents. There would be a total of 142 acres of permanent impact on-site vegetation by project implementation, including a loss of 2.39 acres of coastal sage scrub/non-native grassland, a loss of 0.68 acres of coast live oak woodland, a loss of 0.02 acre of willow woodland, and a loss of 2.53 acres of non-native grassland.

Impacts to non-native annual grassland are considered to be below a level of significance. The removal of 0.01 acre of eucalyptus grove is considered to be beneficial and below a level of significance. Previously developed and graded areas provide little habitat for native species, thus a loss of approximately 11.19 acres would result with implementation of the project and is considered to be below a level of significance.

Implementation of the project would result in the direct impacts to approximately 61.02 acres of Plummer's mariposa lily habitat and 1,793 individuals identified on-site, including one acre of high density habitat. Impacts to the estimated 1,783 individuals are considered significant if left unmitigated. However with mitigation measure (4.3-4), impacts to Plummer's mariposa lilies would be reduced below a level of significance

Regarding impact to wildlife, the FEIR states: Implementation of the project would not result in an impact to any state or federally listed wildlife species. As indicated in Section 4.3.1, specific sensitive species surveys have been conducted for the coastal California gnatcatcher, least Bell's vireo, southwestern willow flycatcher and the California red-legged frog. None of these sensitive species were identified onsite, nor are they expected to occur onsite.

The following mitigation measures were recommended in the certified FEIR to ensure biological resource impacts would be less than significant. If sensitive plant and wildlife species are found on the additional 13 acres, additional mitigation measures shall be developed under approval of the appropriate agencies.

- 4.3-1. An off-site mitigation parcel shall be dedicated to Los Angeles County or a public conservation agency to the satisfaction of Los Angeles County Department of Regional Planning. The mitigation parcel shall be of a minimum size of the collective total of all on-site project sensitive vegetation impacted (but not less than 68 acres) and shall be adjacent to or and contiguous with permanent open space of comparable size;
- 4.3-2. The applicant shall mitigate impacts to 0.03 acre of onsite willow woodland based on recommendations of the project biologist (see Appendix G of the certified FEIR) and to the satisfaction of the California Department of Fish and Game ("CDFG", now California Department of Fish and Wildlife) and the Los Angeles County Department of Regional Planning. The mitigation plans shall be reviewed and approved by these agencies prior to the issuance of grading permits. This mitigation measure will be implemented on the mitigation parcel with 0.12 (Section 3.3.2, Revision C of Final EIR) acre (representing a minimum 4:1 ratio);
- 4.3-3. All eucalyptus shall be removed from open space portions of the project site to enhance the biological values of open space areas, reduce the risk of a canopy fire, and prevent further encroachment of eucalyptus into native habitats to the satisfaction of the Los Angeles County Department of Regional Planning prior to the issuance of grading permits. To avoid impacts

to nesting birds such removal shall be implemented outside of the avian nesting season from March 15 to August 15;

- 4.3-4. Impacts to Plummer's mariposa lily shall be mitigated through a 2:1 replacement of impacted individuals and an additional 2:1 replacement through preservation. Relocated Plummer's mariposa lily will be planted on the mitigation parcel. A qualified biologist/botanist shall oversee all aspects of this mitigation plan per the recommendations of the project biologist (included in Appendix G of the certified FEIR);
- 4.3-5. If earthmoving activities are scheduled to start at the site between April 10 and August 15 (the vireo nesting season) a qualified biologist will perform a one-day survey of the potential vireo habitat for the presence of nesting vireos not more than seven days prior to the start of such earthmoving activities. If any nesting vireos are observed, no work (vegetation clearing, earthmoving, or construction) may occur on the plateau above the riparian habitat within 150 feet of the nest, or in the riparian habitat within 500 feet of the nest. If any nesting vireos are observed, the qualified biologist will monitor activities occurring within 1,000 feet of the nest to ensure compliance with this condition;
- 4.3-6. If earthmoving activities start outside the vireo nesting season (August 16 through April 9), no additional vireo surveys will be required, unless (during the vireo nesting season) said work ceases for a period of more than 15 days before beginning again. In such case, the restart of earthmoving activities will be considered as a new start of earthmoving activities, subject to the condition above;
- 4.3-7. A storm water pollution prevention plan (SWPPP) shall be in place to direct prevention and/or minimization of storm water runoff from the work site during construction to prevent/minimize impacts to riparian/wetland vegetation and its associated species;
- 4.3-8. Special construction methods as recommended by the project bridge engineer (see Appendix D of the certified FEIR) shall be implemented to incorporate clear spans across Devil Canyon for the proposed bridges;
- 4.3-9. Coastal sage impacts of 2.39 acres will be mitigated to the satisfaction of the Los Angeles County Department of Regional Planning through the preservation of a minimum 4.78 acres of coastal sage scrub or coastal sage scrub/chaparral ecotone on the mitigation parcel;
- 4.3-10. Coast live oak woodland impacts of 1.3 acres will be mitigated to the satisfaction of the Los Angeles County Department of Regional Planning through the preservation of 2.6 acres (which represent a 2:1 mitigation ratio) on the project site and the mitigation parcel.
- 4.3-11. All manufactured slopes outside of the irrigated fuel modification zone shall be landscaped with locally indigenous plant materials in accordance with the landscape concept contained in Exhibit 2.9 and to the satisfaction of the Los Angeles County Department of Regional Planning.
- 4.3-12. All impacted oak trees, totaling 42, shall be mitigated (2:1 replacement with 15 gallon trees). All oak tree mitigation shall be monitored by a qualified arborist, in accordance with the

established preservation program included in the Oak Tree Report (see Appendix H of the certified FEIR);

- 4.3-13. Copies of the final Oak Tree Report and the Los Angeles County approved Oak Tree Permit will be maintained on-site during construction. Implementation of work approved by the Oak Tree Permit shall not begin prior to issuance of a grading permit;
- 4.3-14. Prior to any construction activity, the applicant shall have a qualified biologist survey the project site for the presence of any occupied raptor nests, as protected by the Migratory Bird Treaty Act. If such a nest is found, it will be avoided and protected until nesting activity has ended to ensure compliance with Section 3503.5 of the California Fish and Game Code based on the recommendations of the project biologist (see Appendix G of the certified FEIR). During nesting (March 15th to August 15th) occupied nests shall be avoided through implementation of a 300 foot buffer zone for nesting bird and a 500 foot buffer zone for nesting raptors. Should construction activities encroach into these identified buffer zones, noise barriers shall be constructed to minimize noise impacts to the birds and ensure that noise levels do not exceed 65db CNEL;
- 4.3-15. Light poles shall be 14 feet high instead of 26 feet high and all streetlights potentially affecting open space areas shall be fitted with baffles to eliminate direct shine into open space areas. Security lighting shall be low intensity, shielded, directed downward and away from open space areas. Use of motion detectors shall be maximized for outdoor lighting; and
- 4.3-16. Mitigation required for impacts to areas identified within the jurisdiction of the Corps Clean Water Act Section 404 Permit and/or a CDFG Section 1603 Streambed Alteration Agreement shall be determined during agency permitting subsequent to EIR certification. The applicant shall be responsible for the development of a mitigation plan in accordance with the Corps' Mitigation and Monitoring Guidelines.

The FEIR concludes that with implementation of the recommended mitigation measures, no significant impacts to biological resources would occur.

Analysis of the Amended Project.

Since certification of the FEIR by the Board of Supervisors on August 10, 2004, the Planning Commission approved an Amended VTTM (Second Amendment) on July 18, 2012, which proposed a reduction in the number of residential units from 375 to 314, a reduction in grading quantities from 2.2 million to 1.8 million cubic yards, and an increase in open space lots from 71.4 acres to 84.1 acres. In addition, sections of four major drainage courses were left in their natural state by the 2012 Amended Map within the certified FEIR First Addendum.

Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. The Amended Project proposes to maintain the 1.8 million cubic yards of grading, and increase the area of open space lots from 84.1 acres to 84.8 acres. All grading limits and building envelopes will remain the same as those of the certified FEIR First Addendum.

In addition, since certification of the FEIR, the loss of 2.39 acres of coastal sage scrub/non-native grassland (Mitigation Measure 4.3-9), 0.68 acres of coast live oak woodland (Mitigation Measure 4.3-10), and 0.02 acre of willow woodland (Mitigation Measure 4.3-2) have been mitigated by dedication of 160 acres of permanent open space to the Mountains Recreation & Conservation Authority ("MRCA"; Mitigation Measure 4.3-1). Further, all mariposa lily mitigation (Mitigation Measure 4.3-4) has been completed by transplanting all lily bulbs to the MRCA mitigation land.

Applicable permits have been obtained from the U.S. Army Corps of Engineers ("USACE"; 404 Permit SPL-2008-00523-AOA), the Regional Water Quality Control Board ("RWQCB"; 401 Certificate 11-154), and the California Department of Fish and Wildlife ("CDFW"; 1602 Streambed Alteration Agreement 1600-2003-5131-R5), in satisfaction with Mitigation Measure 4.3-16. All scopes of work and conditions stated in these permits will apply to the Amended Project.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on biological resources from those analyzed in the certified FEIR and certified FEIR First Addendum. All remaining mitigation measures will be implemented as proposed in the certified FEIR and the MMP although the project impact has been reduced by the previous certified FEIR First Addendum, and will be further reduced by the Amended Project.

CERTIFIED FEIR SECTION 4.4 - CULTURAL RESOURCES

Summary of Analysis in Certified FEIR

In accordance with CEQA Section 21083.2 and Appendices G and K of the *State CEQA Guidelines*, project impacts to archaeological resources are considered significant if project activities could cause the loss, destruction or other damage to a prehistoric or historic archaeological site that has been identified as unique or important. Further outlined in *State CEQA Guidelines* Appendix G, implementation of the proposed project would result in a significant impact upon cultural resources if the project:

- Causes a substantial adverse change in the significance of a historical or archaeological resource;
- Directly or indirectly destroys a unique paleontological resource or site or unique geologic feature; and
- Disturbs any human remains, including those interred outside of formal cemeteries.

The project site was intensively surveyed on two occasions. Initially, eight archaeological sites were recorded (Bissell and Becker, 1990). The following three sites were thought to be historical in nature: CA-LAN-1740, -1741H, and -1742H. The remaining five sites, (CA-LAN-209, -649, -1743, -1744, and -1745) are all prehistoric. A subsequent survey (W&S Consultants, 2000a) resulted in the identification and recording of two additional prehistoric archaeological sites as shown on Figure 4.4.1 of the certified FEIR: CA-LAN-2826 (W&S-1) and CA-LAN-2827 (W&S-2). In addition, a survey was completed in December 2000 on an additional 13 acres acquired by the applicant subsequent to the initial site surveys. No cultural resources of any kind were identified within this additional property (W&S Consultants, 2000c).

Preliminary assessments of these resources suggested that the seven prehistoric archaeological sites were all intact and had the potential to be significant. Two of the three previously recorded historical sites (CA-

LAN-1741H and -1742H) were found to consist of the foundations of demolished structures that were associated with contemporary trash and debris. Although they appear to be post World War II and possibly may have met the minimum age requirement of 50 years for historical resources, they were found to be entirely lacking in integrity and thus have no significance from an archaeological perspective. Based on these considerations, they were not considered significant or unique cultural resources. The last historical site (CA-LAN-1740H) is a sandstone and mortar bridge that was thought to be potentially significant from historical, architectural and/or engineering perspectives.

Based on the previous surveys and the findings of the Phase I surface survey, Phase II test excavations and determinations of site significance were conducted (W&S Consultants, 2000b). Procedures followed in the collection of data useful for establishing the nature and significance of the prehistoric sites included mapping, surface collecting of artifacts, and test excavation of pits to establish the presence or absence of a subsurface archaeological deposit. Fieldwork at the one historical site was directed towards field documentation through photography, mapping and analysis to determine whether this feature maintained integrity. The eight relevant sites considered during the Phase II excavation and previous work on those sites are summarized in Section 4.4.2

Implementation of the project would not exceed any of the identified *State CEQA Guidelines* (Appendix G) or Los Angeles County *Environmental Document Reporting and Procedures Guidelines* which are the criteria which establish a significant cultural resources impact.

The certified EIR concludes that the project would not result in adverse impacts to significant cultural resources.

Analysis of the Amended Project.

The Amended Project proposes 84.8 acres of open space lots, an increase of 13.4 acres of open space from the certified FEIR (71.4 acres) and an increase of 0.7 acres of open space from the certified FEIR First Addendum (84.1 acres). The grading limits and building envelopes of the Amended Project will remain the same as those of the certified FEIR First Addendum. In addition, sections of four major drainage courses will be left in their natural state by the 2012 Amended Map (Second Amendment) within the certified FEIR First Addendum. Further, the Amended Project will only disturb the areas previously identified for disturbance within the certified FEIR First Addendum.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impacts on cultural resources from those analyzed in the certified FEIR and certified FEIR First Addendum. The recommended mitigation measure 4.4-1 will be implemented as proposed in the certified FEIR and the MMP although the project impact has been reduced by the previous certified FEIR First Addendum, and will be further reduced by the Amended Project.

CERTIFIED FEIR SECTION 4.5 - GEOLOGY AND SOILS

Summary of Analysis in Certified FEIR

As defined in the *State CEQA Guidelines*, project impacts to geological resources are considered significant if any of the following occurred:

- The project would pose an increased risk, which is greater than average for the southern California region, to public safety or destruction of property by exposing people, property, or infrastructure to seismically-induced hazards such as; earthquakes, landslides, mudslides, ground failure and other similar hazards;
- The project results in substantial soil erosion or the loss of topsoil;
- The project is located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse;
- The project is located on expansive soil, creating substantial risks to life or property; and
- Soils are incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water.

The certified FEIR states that no observable Holocene Age faults occur on the project site. Older faulting does occur on-site as existing zones of weakness that may be susceptible to minor displacement as a secondary response to primary faulting along nearby active faults. However, the project has been designed to mitigate this condition through the construction of uniform, engineered fill cap in conjunction with stiffened foundation systems in these locations. The depth of removal and recompaction associated with the construction of these fill caps will be developed as part of the final project grading plans. Therefore, impacts would be less than significant.

Implementation of the project would involve a grading program to excavate an estimated 1.8 million cubic yards of earth with the majority of the cuts less than 40 feet deep. Soils within the project area would be subject to exposure to wind and water erosion during site preparation. However, erosion associated with site preparation would be temporary and would cease upon completion of construction activities. The potential for erosion also exists associated with the sandy terrace and crystalline bedrock materials that would be used to construct fill slopes and for natural slopes above the graded pad and parking areas. Where needed, appropriate slope stabilization would be implemented to mitigate these impacts. No significant erosion impacts would result from the project.

The project would not pose an increased risk, greater than generally accepted under current codes and standards for the southern California region, to public safety with regard to seismic hazards. Nor would the project result in the destruction of a unique geologic feature. The potential for slope instability and erosion does exist with implementation of the project; however adherence to applicable regulations, standards, and procedures would reduce these impacts to less than significant."

Specific mitigation measures (4.5-1 through 4.5-15) are listed in Section 4.5.4 of the certified FEIR.

Analysis of the Amended Project.

The Amended Project proposes 84.8 acres of open space lots, an increase of 13.4 acres of open space from the certified FEIR (71.4 acres) and an increase of 0.7 acres of open space from the certified FEIR First Addendum (84.1 acres). The certified FEIR First Addendum proposed a reduction in grading quantities from the certified FEIR (2.2 million cubic yards) to 1.8 million cubic yards. All grading limits and building

envelopes of the Amended Project will remain the same as those of the certified FEIR First Addendum, including leaving portions of four drainage courses in their natural state (refer to Figure 4.0).

In addition, the Amended Project proposes to remove and relocate six residential lots from an area designated as a geological RUA. By relocating the lots, the residential uses within the RUA have been eliminated (refer to Figure 6.0).

All mitigation measures within Section 4.5.4 of the certified FEIR, and those listed in the MMP, will apply to the Amended Project. As such, the mitigation measures originally approved exceed those that would be required for the certified FEIR First Addendum and the Approved Project.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on site geology and soils from those analyzed in the certified FEIR and certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.6- HYDROLOGY AND WATER QUALITY

Summary of Analysis in Certified FEIR

The project site is located within the 1,608 square mile Los Angeles River Watershed, which is composed of five primary drainage basins, including the Upper Los Angeles River Basin, and discharges into the Pacific Ocean through the Los Angeles/Long Beach Harbor. This basin includes the San Fernando Hydrographic Unit, which in turn, is comprised of five tributary drainages, including Bell Canyon. The Bell Canyon drainage includes the Browns Canyon Wash, which is the receiving drainage for storm water runoff from the project site, via Devil Canyon.

The project site is located within a 325-acre sub-drainage area tributary to the Devil Canyon/Browns Canyon drainages. The site constitutes 235 acres of that sub-drainage area, of which 226.3 acres discharge into Devil Canyon, and 8.7 acres discharge through a 30-inch pipe into Caltrans (SR-118) right-of-way and into Brown Canyon.

The project site is subject to the following regulatory oversight with regard to hydrology and water quality.

- **Federal Clean Water Act (NPDES):** Established regulations for municipal and industrial storm water discharges under the National Pollutants Discharge Elimination System (NPDES) program, which requires NPDES permits for storm water discharges from storm drain systems⁵ to waters of the United States.
- **Standard Urban Storm Water Mitigation Plan:** The municipal storm water NPDES permit issued to Los Angeles County by the Los Angeles RWQCB requires the development and implementation of a program addressing storm water pollution issues in development planning for private projects. This requirement is based on federal and state statutes, including: Section 402 (p) of the Clean Water Act, Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990, and the California Water Code. The Standard Urban Water Mitigation Plan (SUSMP) was developed as part of the NPDES program to address storm water pollution from new development by the private sector. This SUSMP

contains a list of the minimum required Best Management Practices (BMP's) that must be used for a designated project.

As stated in the certified FEIR, a significant project impact would occur if one or more of the following were to occur:

- The peak storm water runoff from the site after development (Q50c) would exceed the existing peak runoff (Q50bb);
- Peak runoff from the site would exceed the capacities of existing storm drain structures and/or drainage courses;
- Peak runoff from the site would increase high water elevations within existing drainage courses;
- The project would cause flooding of adjacent or downstream properties;
- The project would increase existing storm water runoff pollutant loads, or introduce new pollutants, which would be discharged into existing drainage courses;
- The project would adversely impact those Total Maximum Daily Loads (TMDL) criteria within the Los Angeles River Watershed which are listed in the Unified Watershed Assessment (UWA); and
- The project failed to employ BMP's and otherwise not comply with the Urban Storm Water Mitigation Plan ("USWMP").

The certified FEIR further states that although peak storm water runoff from these pervious surfaces would increase during significant storm events, the total peak storm water runoff volume from the entire drainage area, including the site after development, would be reduced because of the removal of approximately 4,590 cubic yards of solid (bulk and burn) materials by four proposed debris basins (see Figure 4.6.2 of the certified FEIR), and the removal of 44.2 acres of vegetation for building and paving. Specifically, the total peak storm water runoff after development from the drainage area discharging through Location "A" will be reduced from Q50bb = 876.4 cubic feet per second (cfs) to Q50c = 458.0 cfs. In addition, peak storm water runoff after development discharging at Location "B" will be reduced from Q50bb = 61.5 cfs to Q50c = 48.2 cfs. Therefore, the existing 30-inch CMP will still be adequate to accommodate the storm water discharge after development.

As a result of this reduction in the volume of peak storm water runoff, downstream drainages would not be adversely impacted in regard to increased peak flow, velocity or water surface elevations.

The certified EIR states that the project would be constructed to the standards and specifications of the Los Angeles County Flood Control District and the Department of Public Works. In addition, the project would be designed and constructed in compliance with the Standard Urban Storm Water Mitigation Plan For Los Angeles County and Cities In Los Angeles County (SUSMP), NPDES permit and all other applicable state regulations.

A Storm Water Pollution Prevention Plan (SWPPP) would be prepared, utilizing BMP's, as listed in the SUSMP, to ensure compliance with the above regulations both during and after construction. BMP's would include measures which would prevent or minimize storm water pollutants of concern, including the TMDL criteria specified in the Watershed Management Initiative as it pertains to the Los Angeles River Basin.

Implementation of these BMP's will prevent or decrease several TDML pollutants from discharging into the Los Angeles River Watershed, including the following:

- Trash, particularly organic materials due to construction of debris basins and catch basin inserts
- Nitrites (NH₃) due to the reduction in discharge of organic materials

In addition, the project would be served by a public sanitary sewer system, thereby precluding pollution (coliform) of drainage courses from domestic sewage discharge.

Although some hydrocarbons (oil) from automobiles can be expected to be deposited onto road surfaces under normal operations, provisions will be made to filter out these hydrocarbons within the "first flush" of a storm event to a less than significant level.

A SUSMP shall be developed for the project site identifying any pollutant sources that may affect storm water quality after project completion. The following measures shall be included in the SUSMP:

- Inserts shall be included in catch basins and continuous deflection units to filter storm water runoff prior to discharging to the ocean storm drain system, consistent with Compliance Strategies for trash reduction implementation measures of the Draft Basin Plan, *Trash Total Maximum Daily Loads for the Los Angeles River*, dated January 22, 2001;
- Catch basins and storm drain inlets shall be labeled "No Dumping – Drains to Ocean" to discourage illegal dumping;
- Streets within the proposed residential development shall be swept on a regular basis;
- Signs shall be posted through the proposed development with prohibitive language and/or graphical icons to discourage illegal dumping;
- Non-toxic pesticides and fertilizers shall be used in landscaped areas of the project;
- All graded slopes shall be planted on a timely basis to prevent erosion;
- Homeowners shall be provided with information from the County Department of Public Works (DPW) Environmental Planning Division's concerning recycling of household products, disposal of hazardous wastes, disposal of yard wastes, tire recycling, and preventing pollution of storm drain systems with trash; and
- Require developer-owners to execute and record the County DPW's *Maintenance Covenant For Standard Urban Stormwater Mitigation (SUSMP)* pursuant to Section 106.4.3 of the County Building Code and Title 12, Chapter 12.8 of the County Code.

The certified FEIR concludes that implementation of the proposed project would result in a decreased flow due to inclusion of four debris basins in the project design. The project would be constructed to the standards and specifications of the Los Angeles County Department of Public Works. In addition, a SUSMP would be developed for the project to further ensure impacts would be less than significant. The project is not anticipated to result in a significant adverse impact on the capacities of existing or proposed storm drain facilities, nor is it anticipated to adversely impact downstream hydrology or water quality.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314, a reduction in grading quantities from 2.2 million to 1.8 million cubic yards, an increase in open space lots from 71.4 acres to 84.1 acres. In addition, sections of four major drainage courses traversing the property were left in their natural state by the 2012 Amended Map within the certified FEIR First Addendum.

Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. The Amended Project proposes to maintain the 1.8 million cubic yards of grading, and increase the open space lots from 84.1 acres to 84.8 acres. All grading limits and building envelopes will remain the same and sections of four major drainage courses will remain in their natural states same as in the certified FEIR First Addendum.

As a result of the reduction in residential lots and the increase in open space, including reaches of four natural drainage courses, the area of pervious surfaces has been reduced, thereby reducing peak flow runoff. In addition, the decrease in residential lots will decrease the amount of solids associated with urban storm water runoff, and also reduce the trace amounts of hydrocarbons on the streets.

Similar to the certified FEIR First Addendum, the Amended Project will not alter any existing drainage course, or modify any site drainage patterns. Further, the Amended Project will comply with the requirements of the all Drainage Concepts, Hydrology Studies, and Standard Urban Stormwater Mitigation Plans (SUSMP), which were conceptually approved on 11/25/2003, 12/28/2006, 08/23/2007, and 08/29/2011, including compliance under the County's NPDES Permit (MS4 Permit) to the satisfaction of the County Department of Public Works. In addition, a SWPPP will be prepared, utilizing BMP's, as listed in the SUSMP, to ensure compliance with the above regulations both during and after construction.

Since certification of the FEIR, the project has received permits from the USACE, the RWQCB, and the CDFW, as required by federal, state and County regulations.

All mitigation measures (4.6-1 through 4.6-4) listed in the certified FEIR, and those required by the above-listed permitting agencies, will be applied to the Amended Project.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on site hydrology from that analyzed in the certified FEIR and certified FEIR First Addendum with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.7 - NOISE

Summary of Analysis in Certified FEIR

The State Department of Health Services has prepared Land Use Compatibility Guidelines for evaluating community noise impacts. The County of Los Angeles has adopted local guidelines which are consistent with the state community noise guidelines for use in evaluating the compatibility of various land use types with a range of noise levels. A CNEL value of 65 dB(A) is considered the dividing line between clearly acceptable

and normally acceptable noise environments for many noise sensitive receptor land uses, including residential uses such as those within the project area.

An interior CNEL of 45 dB(A) is mandated by multiple family dwellings in Title 24 of the California Code of Regulations. In 1988, the State Building Standards Commission recommended that the 45 dB CNEL interior standards be expanded to include all habitable rooms for all residential occupancy, including single family. The County of Los Angeles has required a 45 dB(A) CNEL interior standard for all occupancies well before the adoption of the statewide guidelines. Since typical noise attenuation within residential structures with closed windows is about 20 dB, an exterior noise exposure of 65 dB CNEL is generally the noise land use compatibility guideline for new residential dwellings in threshold where noise begins to substantially interfere with enjoyment of any outdoor recreational amenity. Mitigation of exterior noise to at least 65 dB CNEL is normally required for residential projects in Los Angeles County for any usable outdoor space.

Construction noise sources are not strictly relatable to a 24-hour community noise standard, because they only occur during selected times and the source strength varies sharply with time. Further, construction activities would not represent a chronic permanent noise source. To abate the potential nuisance from construction noise, especially in very close proximity to any nearby noise-sensitive development, the Los Angeles County Noise Ordinance (Section 12.08.440) limits the hours of allowable construction activities and establishes noise performance standards at the nearest residential structures.

Varying levels of construction noise may be heard in different parts of the project site during the project's total construction period. The noise strength of construction equipment ranges widely as a function of the equipment used. Further, short-term variations are strongly influenced by topographical factors that may change during the course of the construction activities. As noise levels generated by heavy equipment can range from approximately 68 dB(A) to noise levels in excess of 100 dB(A) when measured at 50 feet. However, noise levels would diminish rapidly with distance from the construction area at a rate of approximately 6.0 dB(A) per doubling distance.

Noise levels generated during the construction of the project would primarily affect the off-site residents of the Lower Twin Lakes development. Any locations with an uninterrupted line of sight to the construction noise sources could periodically be exposed to temporary noise levels which could exceed the County's Noise Ordinance standards for construction equipment. However, such events would be intermittent due to the intervening terrain. However, the terrain of the project site would shield nearby Twin Lakes residents. In addition, enforcement of the noise ordinance would provide a reasonable measure of protection for nearby residences in those localized instances where major earthwork would occur within close proximity.

With the combination of an adequate distance buffer for most major earthwork associated with the project, terrain shielding for many residential units adjacent to the site, and compliance with County ordinances, construction activities would not result in a significant noise impact on the project site or the adjacent Twin Lakes community.

Without consideration of background freeway noise, the project would create a maximum off-site traffic noise impact of 6.9 dB above the future no project contribution along Mayan Drive east of Topanga Canyon Boulevard. However, this roadway has a high freeway background noise level that would mask any local

roadway noise changes. When the background freeway noise is considered, the project increase would be less than 1.0 dB.

Per the *Land Use Compatibility Guidelines* utilized by the County, the project would result in a significant impact if it causes on-site exterior locations to be exposed to noise levels above County Noise Ordinance standards of 65 dB CNEL. Significant off-site noise impacts would occur when:

- An increase of 5.0 dB(A) or greater noise level occurs from project related activities if levels remain within the same land use compatibility classification; or
- An increase of 3.0 dB(A) or greater in noise level occurs from project related activities which results in a change in land use compatibility classification.

All construction activity occurring on the project site shall adhere to the requirements of the County of Los Angeles Noise Ordinance, Title 12, Section 12.08.440. All stationary and point sources of noise occurring in the project site shall adhere to the requirements of the County of Los Angeles Ordinance No. 11743.

Implementation of the project would not result in significant short-term noise impacts associated with construction activities, due to intervening terrain and compliance with County noise ordinances. Traffic noise would not result in significant impact. On-site noise exposure associated with the project would not be significant with implementation of the above mitigation measures.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314, a reduction in grading quantities from 2.2 million cubic yards to 1.8 million cubic yards, an increase in open space lots from 71.4 acres to 84.1 acres. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. The Amended Project proposes to maintain the 1.8 million cubic yards of grading, and increase the open space lots from 84.1 acres to 84.8 acres.

The Amended Project proposes a substantially reduced amount of grading as the certified FEIR and a similar amount as the certified FEIR First Addendum, resulting in less or similar short term construction noise and long term traffic noise. The projected construction schedule is anticipated to remain the same as that of the certified FEIR First Addendum Approved Project.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on site-generated noise from that analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures (4.7-1 through 4.7-3) to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.8 – PUBLIC SERVICES - FIRE PROTECTION

Summary of Analysis in Certified FEIR

The project would receive fire protection services from County Fire Station No. 75, located at 23310 Lake Manor Drive in Chatsworth. The station is approximately 5.4 miles southwest of the project site and maintains a three-person engine company. Also, the County Fire Department has an automatic aid agreement with the City of Los Angeles in the event that additional services are needed during an incident. The first-due response unit to the project site would be City Station No. 96, located at 21800 Marilla Avenue in Chatsworth, approximately three miles south of the project site. In addition to Station No. 96, fire protection services would also be provided by City Station No. 28, located at 11641 Corbin Avenue in Porter Ranch, approximately two miles east of the project site.

The project is located within a Fire Zone 4, Very High Fire Hazard Severity Zone (VHFHSZ). The County of Los Angeles General Plan defines a Fire Zone 4 area as one which has the highest fire hazard potential. Such areas are susceptible to wildland fires because of the hilly terrain, dry weather conditions, and nature of plant cover. The Forester and Fire Warden of the County Fire Department has designated a variety of regulatory programs and standards including an approved fuel modification plan, directed toward the abatement of this fire hazard and reduction of risk to tolerable levels.

As defined in the *State CEQA Guidelines* the project would result in substantial adverse physical impacts associated with the provision of new or physically altered fire protection agencies, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives.

The project would have additional significant impact on fire and emergency services if:

- It generates demand for additional fire protection or emergency medical service that substantially exceeds the staff and equipment capabilities of any County Fire Department stations serving the property;
- It does not comply with applicable County Fire Department Code and ordinance requirements or standards for construction, water mains, fire-flow and fire hydrants; or
- The proposed project would impair emergency access to the site or cause an increase in emergency response times.

Development of the project would result in the construction of residential uses in an area designated as Fire Zone 4 (Very High Fire Hazard Severity Zone). To mitigate the potential spread of dry brush or wildfire that could occur in this area, it is required that the project applicant implement a fuel modification plan to minimize or retard the spread of dry brush and wildfire into a development area. With implementation of the approved Fuel Modification Plan, wildfire impacts would be reduced to less than significant.

The County of Los Angeles Fire Department has determined that development of the project would require 44 new fire hydrants, located throughout the project site. As indicated, the minimum fire flow requirement is 1,250 gallons per minute (gpm) for two hours with a current required minimum residual pressure of 20 psi. It has been determined by the LACFD that the proposed system would be able to provide fire flow to all

hydrants at pressures greater than this required minimum. No significant impacts on fire-flow requirements or fire regulations would occur with implementation of the project.

Although no significant impacts are anticipated with regard to implementation of the project, the following mitigation measures have been recommended to ensure impacts are minimal.

- 4.8-1. The project shall incorporate the following County Fire Department requirements regarding access, water mains, fire flows, fire hydrants, and brush clearance into project design:
 - Every building constructed shall be accessible to fire department apparatus by way of access roadways, with an all weather surface of not less than the prescribed width, unobstructed, clear-to-sky. The roadway shall be extended within 150 feet of all portions of the exterior walls when measured by an unobstructed route around the exterior of the building.
 - All bridges required to be used as part of a fire access road shall be constructed and maintained in accordance with nationally recognized standards and designed for a live load sufficient to carry a minimum of 75,000 pounds.
 - Access to existing fire fighting motorways shall be maintained.
 - Fire hydrant spacing shall be 600 feet and shall meet the following requirements:
 - No portion of lot frontage shall be more than 450 feet via vehicular access from a public fire hydrant.
 - No portion or structure should be placed on a lot where it exceeds 750 feet via vehicular access from a properly spaced public fire hydrant.
 - When cul-de-sac depth exceeds 450 feet on a residential street, hydrants shall be required at the corner and mid-block. Additional hydrants shall be required if hydrant spacing exceeds specified distances.
- 4.8-2. Streets or driveways within the development shall be provided with the following widths in accordance with County Fire Department and Department of Public Works standards:
 - Provide 36 feet width on all collector streets and those streets where parking is allowed on both sides.
 - Provide 34 feet width on cul-de-sacs up to 700 feet in length. This allows parking on both sides of the street.
 - Provide 36 feet width on cul-de-sacs from 701 to 1,000 feet in length. This allows parking on both sides of the street.
- 4.8-3. All dwelling units shall be fully sprinkled per NFPA pamphlet 13 D to offset potential response time impacts.
- 4.8-4. The proposed project shall comply with the fuel modification plan, which has been approved by the Forestry Division of the Fire Department (see Appendix E of the certified FEIR).
- 4.8-5. The proposed project shall comply with all applicable County Fire Code and Ordinance requests including standards for construction, installation of sprinkler and alarm systems, fire extinguishers, and emergency exits.

As stated above, the project would not conflict with applicable County Fire Department Code and ordinance requirements or standards for construction, access, water mains, fire-flow and fire hydrants and would not impair emergency access to the site or cause an increase in emergency response times. Impacts on fire protection services would not be significant. Mitigation measures are recommended to ensure impacts would remain minimal.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units.

All mitigation measures (4.8-1 through 4.8-5) previously identified within the certified FEIR, including fuel modification plans and requirements, will be implemented as part of the Amended Project, including the construction of a helispot in the northeasterly portion of the project.

As with the certified FEIR and the certified FEIR First Addendum, the Amended Project, including the recreation center, would be subject to County Building and Safety and Fire Code requirements for Fire Zone 4, as well as conditions of approval specified by the Los Angeles County Fire Department.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on fire protection services from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the approved certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.9 - PUBLIC SERVICES - POLICE PROTECTION

Summary of Analysis in Certified FEIR

Police protection services within the County are provided by the Los Angeles County Sheriff's Department. The project would be served by the Lost Hills/Malibu Station which is located at 27050 Agoura Road in Calabasas, approximately 25 miles southwest of the project site.

As defined in the *State CEQA Guidelines* the proposed project would result in substantial adverse physical impacts associated with the provision of new or physically altered police protection agencies, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives.

Additionally, project impacts on police protection services would be considered significant if either of the following would result:

- The population increase resulting from the project substantially reduces the standard officer to population ratio of the County (one officer per 1,000 populations) in which the project is located.
- Emergency response times are inhibited by increasing roadway congestion within an area either during construction or upon post-construction occupancy.

As stated in the certified FEIR, the addition of 538 residences would increase calls for police protection service to this area and may necessitate a change in the Lost Hills/Malibu Station's deployment of deputies. However, implementation of the project would serve to increase the existing funding mechanisms (i.e., property taxes) for any additional officers required to serve the project area. Therefore, impacts would not be considered significant.

Emergency access to the project would be provided by the existing and proposed street system. Further, implementation of the project would improve emergency access to the existing Twin Lakes community. The project would be designed in accordance with Los Angeles Municipal Code requirements, including regulation of street widths, street lighting, and street signage. Implementation of mitigation measures would reduce impacts on all affected intersections to less than significant. Therefore, no significant impact with regard to emergency access would result.

Although no significant impacts are anticipated, the following mitigation measures are recommended to ensure impacts upon police protection services remain less than significant:

- Prior to recordation of the Final Tract map, the applicant shall provide the Los Angeles County Sheriff's Department's with a diagram of the project, including access routes, addresses, and any information that might facilitate police response.
- (Note: Although not part of the original DEIR, the certified FEIR included the requirement to construct a Sheriff's Storefront Facility on the site)

Although this increase would not result in a significant change in the current officer to resident ratio, the Sheriff's Department indicated implementation of the project would require additional officers. However, the increase in existing funding mechanisms (i.e., property taxes) would provide for the additional personnel. Therefore, no significant impacts are anticipated.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units.

All mitigation measures (4.9-1 through 4.9-3) previously identified will be implemented as part of the Amended Project, including the construction of a Sheriff's Storefront Facility in the southwesterly portion of the project to enhance police services for the project and the surrounding community.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on police protection services from those analyzed in the certified FEIR and certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.10 - PUBLIC SERVICES - SCHOOLS

Summary of Analysis in Certified FEIR

The project site currently has no student population. LAUSD provides primary and secondary public education services for the project area. The project is located within the attendance boundaries of four public schools (see Figure 4.8.1 of the certified FEIR). These schools are: Chatsworth Elementary School (Grades K-5); Germain Elementary School (Grades K-5); Lawrence Middle School (Grades 6-8); and Chatsworth Senior High School (Grades 9-12).

In addition, two private schools serve the project area: Sierra Canyon School (K-12 grades), and Chatsworth Hills Academy (K-8 grades).

As defined in the *State CEQA Guidelines* the proposed project would result in substantial adverse physical impacts associated with the provision of new or physically altered schools, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, or other performance objectives.

In addition, based on criteria established by the County and input from LAUSD, impacts associated with the project upon school facilities would be considered significant if any of the following occurred:

- The population increase resulting from the project, based on the increase in residential units, would create or exacerbate over capacity conditions at a school that serves the project or create capacity problems at the district level.
- Population increases from the project would result in construction of new school facilities, a major redistribution of students or classrooms, major revisions to the school calendar, or other capacity-accommodating actions.

There are two elementary schools which students from the project could attend. The project site is located within the existing boundaries for both Chatsworth Elementary School and Germain Elementary School. These schools, projected to have 125 and 228 student spaces available, respectively, would have sufficient space to accommodate all 231 elementary students generated by the project (see Table 4.10.3). Lawrence Middle School, which is projected to have space to accommodate 914 additional students, would have sufficient space for the 135 students generated by the project. Finally, Chatsworth Senior High School is projected to have space to accommodate an additional 1,291 students and would also have sufficient space for the 184 students generated by the project. Therefore, the estimated elementary, middle, and high school students generated as a result of the project are not anticipated to result in significant impacts to LAUSD elementary, middle, or high school services.

Section 65995 of the California Government Code requires developers to pay a one-time fee for capital acquisitions and improvements. Such fees are paid at the time building permits are issued. The fees are paid into a general fund and may or may not be used to offset the impacts of the development generating the fees. California Government Code Section 65995(b) establishes the maximum school impact fee at \$3.50 per square foot for new residential building space. Currently, specific designs and square footage for the single-family residences has not been developed. However upon issuance of a building permit, the developer would

pay the applicable fees to offset potential capacity deficits in local schools. Therefore, as stated in the FEIR, no significant impact would result and no additional mitigation measures would be necessary.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units.

As such, the proposed modification proposes no significant change in project improvements that would increase impact on school services from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.11 - PUBLIC SERVICES - LIBRARY SERVICES

Summary of Analysis in Certified FEIR

The Los Angeles County Public Library operates facilities and services Countywide in both unincorporated and incorporated areas of the County. The Chatsworth Branch Library is located at 21052 Devonshire Street, Chatsworth.

Significance threshold criteria for library services are not specified in either the *State CEQA Guidelines* or the Los Angeles County *Environmental Document Reporting Procedures and Guidelines*. Library facilities and materials are considered a part of the Development Monitoring System of Los Angeles County, which relies upon the service provider to determine the requirements of new development relative to the service provided. In keeping with this procedure, this impact analysis relies upon the County of Los Angeles Public Library standards for library service as a threshold of project significance. Therefore, impacts associated with the project upon library facilities would be considered significant if any of the following occurred:

- The population increase resulting from the project, based on the increase in residential units, would create or exacerbate over capacity conditions at a library that serves the project.

Development of the project would increase demand for library services, thereby increasing the need for additional facilities and materials (e.g., books, periodicals, audio tapes, videos, etc.).

To ensure sufficient library capacity is available for project generated students, Los Angeles County Ordinance (Section 22.72 Library Facilities Mitigation Fee) requires that new residential subdivisions pay a library fee in effect at the time, when permits are pulled, per residential unit for the project area) to ensure that new projects mitigate impacts to library facilities. As the developer would pay the applicable fees to offset potential impacts, no significant impact is anticipated. In addition, no additional mitigation beyond that which is identified for the project is recommended for cumulative development projects, and cumulative impacts would be less than significant.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum with certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on library services from those analyzed in the certified FEIR and certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.12 – TRANSPORTATION/TRAFFIC

Summary of Analysis in Certified FEIR

The project site is located in the unincorporated hillside area of Los Angeles County, north of SR-118 in between where Topanga Canyon Boulevard and Canoga Avenue currently terminate at SR-118. While the project site is located in an unincorporated area of Los Angeles County, some study intersections are located within the City of Los Angeles. Therefore, the traffic analysis follows County of Los Angeles and City of Los Angeles traffic study guidelines and has been approved by County of Los Angeles.

Traffic study application of the County's and City threshold criteria "with Proposed Project" scenario indicates at three study intersections are anticipated to be significantly impacts by the project during the A.M. and P.M. peak hours.

The study intersections were determined by LADOT staff, and confirmed with staff from the Los Angeles County Department of Public Works (LACDPW), Traffic and Lighting Division. While the project is located within an unincorporated area of Los Angeles County, 11 of the 13 study intersections are located within the City of Los Angeles.

A detailed evaluation of existing and future traffic conditions was completed for each of the following 13 study intersections:

- Topanga Canyon Boulevard & Poema Place/Mayan Drive (County)
- Topanga Canyon Boulevard & SR-118 WB On/Off Ramps (County and CMP monitoring station)
- Topanga Canyon Boulevard & SR-118 EB On/Off Ramps
- Topanga Canyon Boulevard & Santa Susana Pass Road
- Topanga Canyon Boulevard & Chatsworth Street
- Topanga Canyon Boulevard & Devonshire Street (CMP monitoring station)
- Canoga Avenue & Rinaldi Street
- Canoga Avenue & Chatsworth Street
- Canoga Avenue & Devonshire Street

- De Soto Avenue & SR-118 WB & EB On/Off Ramps
- De Soto Avenue & Chatsworth Street
- De Soto Avenue & Devonshire Street

The project is expected to create significant impacts because it exceeds the City's impact thresholds at the following intersections:

- Topanga Canyon Boulevard and SR-118 WB On/Off-ramps
- Topanga Canyon Boulevard and SR-118 EB On/Off-ramps
- De Soto Avenue and Chatsworth Street

Project-related significant impact is anticipated at the intersection of Topanga Canyon Boulevard & SR-118 WB On/Off-ramps during the A.M. and P.M. peak hours. In addition, the project is expected to result in significant impacts at the three study intersections. The following mitigation measures are recommended to reduce impacts to less than significant levels:

- The applicant shall install a traffic signal at the intersection of Topanga Canyon Boulevard and Poema Place/Mayan Drive. The traffic signal shall be interconnected and operated in conjunction with the existing traffic signal at the Topanga Canyon Boulevard & SR-118 WB On/Off-ramps.
- The applicant shall widen and restripe the WB SR-118 off-ramp to provide exclusive right-turn lane. This would result in a left-turn lane, a shared through/left-turn lane, and a right-turn only lane in the westbound approach.
- The applicant shall widen and restripe the westbound Mayan Drive approach to County Collector Street standards to provide a second left turn lane. This would result in a left-turn lane and a shared through/left-turn lane in the westbound Mayan Drive approach.
- The applicant shall widen and restripe the EB Poema Place approach to provide a second right-turn lane. This would result in a right-turn lane and a shared through/right-turn lane in the eastbound Poema Place approach.
- The applicant shall contribute to the City of Los Angeles' Automated Traffic Surveillance and Control (ATSAC) system for the following intersections:
 - Topanga Canyon Boulevard and SR-118 EB On/Off-ramps.
 - De Soto Avenue and Chatsworth Street.

Therefore, with implementation of the recommended mitigation measures (4.12-1 through 4.12-13), the project would not result in significant impacts to area traffic.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. Therefore, there has been a significant reduction in the density of this

project, and corresponding reduction in the construction and operational traffic generation data used in the certified FEIR.

The Amended Project proposes a recreation center to be located on a site previously approved for four single family residential lots and a short cul-de-sac street serving these lots. The building pad of the recreation center site will coincide with the combined building pads and cul-de-sac, resulting in no change in construction traffic. Consequently, construction impacts are anticipated to be comparable to the Approved Project as discussed in the certified FEIR First Addendum.

The addition of an on-site recreation center for use by the project residents is anticipated to reduce the number of vehicle trips by residents who would seek similar recreational opportunities off-site in the absence of an on-site facility. Additional off-site vehicle trips generated by the recreation center personnel are anticipated to be minimal.

In addition, since certification of the FEIR, all mitigation measures for the Topanga Canyon Boulevard/ SR-118 On/Off-ramps/Poema Place intersection have been completed, without consideration of the reduction in project density, and have been accepted by Caltrans and the County.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on traffic from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR and MMP.

CERTIFIED FEIR SECTION 4.13 – UTILITIES AND SERVICE SYSTEMS - WATER SUPPLY

Summary of Analysis in Certified FEIR

This analysis summarizes the findings and conclusions of *Water System Design Report for Tentative Tract No. 53138, Deerlake Ranch*, prepared by the LVMWD. In addition, water supply and demand information was obtained from the Urban Service Analysis prepared by Los Angeles County Department of Regional Planning, the LVMWD *Population Growth, Residential Development and Employment Activity Report* (March 31, 1996), the *Potable Water System Master Plan for Las Virgenes Municipal Water District* (December 1999) and the *Las Virgenes Municipal Water District Urban Water Management Plan* (adopted December 12, 2000).

In accordance with the California Water Code, Division 6, Part 2.6, “every urban water supplier shall prepare and adopt an Urban Water Management Plan (UWMP)” to pursue to efficient use of available supplies and to ensure the appropriate level of reliability in water service to meet customers’ needs during normal, dry and multiple dry water years.

A key element of the UWMP is to determine future demands and the ability of the server to meet those demands. The projection data for future water demand in the LVMWD UWMP is based on the potential buildout or properties consistent with the land use elements of the Los Angeles County, and cities of Agoura Hills, Calabasas, Hidden Hills, and Westlake Villages General Plans; as well as the population, housing and employment forecasts of the Southern California Association of Governments (SCAG). Based on data generated from the above sources, which is presented in the LVMWD *Potable Water System Master Plan for*

Las Virgenes Municipal Water District (December 1999), the LVMWD developed a management plan which provides for the continued service of potable water resources to its service area consistent with the California Water Code.

The project site is currently served by the Twin Lakes Subsystem which consists of existing water distribution pipelines; a pumping station; and two water tanks. This subsystem is currently connected to MWD's transmission main, identified as the "SC LV-3 Turn Out" which is located just below the Twin Lakes Pump Station. The SC LV-3 Turn Out is, in turn, connected to the MWD's West Valley Feeder pipeline.

The existing pipelines range in size from 6 to 18 inches and receive potable water from the Twin Lakes Tanks, which are located approximately one mile north of the Twin Lakes Pump Station. The pump station maintains the gradient (water level) in the Twin Lakes Tanks of 1,584.75 feet with a combined capacity of 2.0 million gallons (mg). The Twin Lakes Subsystem has an existing pumping capacity of 2,050 gpm.

In assessing the significant impacts upon water resources for the project, the *State CEQA Guidelines* consider whether sufficient water supplies are available to serve the project from existing entitlements and resources, or if new or expanded entitlements are necessary. Similarly, the County of Los Angeles *Environmental Document Reporting Procedures and Guidelines* focuses on adverse impacts on water availability when the project cannot be served by the existing water system facilities due to:

- Inadequate capacity in water lines, piping systems, water treatment and/or water storage facilities, and/or
- Inadequate water supplies to meet domestic and/or fire flow demands.

The project would receive its potable water from the District's existing 1,585-foot gradient Twin Lakes Subsystem via the existing Twin Lakes Pump Station and Twin Lakes Tanks. This would require the construction of a new 16-inch pipeline, connecting to the proposed water system directly to the Twin Lakes Tanks, with no connections in between. Such connection would require that the pipeline not exceed the bottom elevation of the smaller Twin Lakes Tank of 1,555 feet. Several additional pipelines ranging in size from six to 14 inches, would also be installed, underlying the project site at various locations.

The LVMWD recommends that a small pump station with a hydropneumatic tank be installed to provide an effective hydraulic gradient (pressure zone) of 1,656 feet to provide several proposed homes at the higher elevations with a minimum pressure of approximately 76 psi.

Although no significant impacts are anticipated with the project, the following mitigation measures are recommended to further reduce water consumption and ensure impacts would be less than significant:

- 4.13-1. Water system distribution facilities shall meet the LVMWD specifications and standards.
- 4.13-2. The project developer shall install low-flush toilets and low-flow showerheads, consistent with the LVMWD requirements.
- 4.13-3. The project shall comply with Water Conservation Ordinance Nos. 11-86-161 and 1-93-205.

4.13-4. Water conserving measures in landscape management shall include:

- Use of drought-tolerant plantings.
- Installation of efficient irrigation systems that minimize runoff and evaporation and maximize the water that will reach the plant roots. Setting of automatic irrigation systems to ensure irrigation during early morning or evening hours. Resetting of automatic irrigation system to water less often in cooler months and during the rainfall season so that water is not wasted by excessive landscape irrigation

The existing pump station and tanks have the capacity to accommodate the project potable water demand requirements. The project would not have a significant effect on LVMWD ability to meet demand for services prior to, or following, implementation of the recommended mitigation measures. Therefore, implementation of the recommended mitigation measures would further reduce water consumption demands of the project and impacts would remain less than significant.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. Therefore, there has been a significant reduction in the residential density of this project and corresponding reduction in water demand.

The certified FEIR would result in an estimated average water demand of approximately 420,480 gallons per day (“gpd”). The certified FEIR First Addendum would result in an estimated average water demand of approximately 375,490 gpd.¹ According to the Water System Design Report for Amended Vesting Tentative Tract No. 53138 Deerlake Ranch, the Amended Project would result in an estimated average water demand of 315,360 gpd.² There are currently no reclaimed water facilities adjacent to the proposed development as no infrastructure is present in the area. As such, the mitigation measures originally approved exceed those that would have been required for the certified FEIR First Addendum and the Approved Project. As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on water demand from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures (4.13-1 through 4.13-4) to be implemented as stated in the certified FEIR. In addition, implementation of the applicable recommendations of the Water System Design Report for Amended Vesting Tentative Tract No. 53138 Deerlake Ranch would further reduce water consumption demands of the Amended Project and impacts would remain less than significant. Additionally, the Project Applicant received a will serve letter from the LVMWD, assuring the Amended Project connection to the water system of the district if the proponent satisfied all terms and conditions for services as set forth in the LVWMD’s Code. If the Project Applicant’s property cannot be served from an existing water main, then the Project Applicant shall provide for the extension of the facilities necessary to provide such service in the manner set forth in Title 3 of the LVMWD Code, Ordinance No. 11-86-161.³

¹ The certified FEIR used 737.5 gallons per day (gpd)/unit to calculate the estimated water demand. In addition, the certified FEIR used a conservative water demand generation of 2,690 gpd/acre of landscaped area.

² Water System Design Report for Amended Vesting Tentative Tract No. 53138 Deerlake Ranch, Las Virgenes Municipal Water District, Table 3, Phases 1, 2, & 3 Estimated Potable Water Demand for Amended Vesting Tentative Tract No. 53138, prepared by AECOM Technical Services, Inc., dated May 2015. Average Day Demand of 219 gallons per minute X 1,440 gallons per day = 315,360 gpd.

³ Conditional Statement of Water Service, prepared by Phyllis Southard, Planning & New Development Technician, LVMWD, dated May 8, 2013.

CERTIFIED FEIR SECTION 4.14 - UTILITIES AND SERVICE SYSTEMS - WASTEWATER

Summary of Analysis in Certified FEIR

There is currently no sewage generation on the project site, and no portion of the property connects to any off-site sewer. Although the project is located within the LVMWD service area, the project site is not included within LVMWD Sanitation Improvement District (SID) "B," which presently covers only those areas west of Topanga Canyon Boulevard and south of SR-118. Annexation of the project site to SID "B" is currently underway. **(Note: The annexation to SID "B" was completed subsequent to certification of the FEIR)**

There are no LVMWD-owned sewage treatment and disposal facilities available to serve SID "B". Therefore, LVMWD has a contractual agreement with the City of Los Angeles to accept SID "B" sewage, which will include the project site upon completion of the annexation proceedings. Sewage from SID "B" is treated at the Hyperion Facility in El Segundo or the Tillman Water Reclamation Plant in Van Nuys, which serves the San Fernando Valley and has a treatment capacity of 80 million gallons per day.

According to the *State CEQA Guidelines*, a project is considered to have a significant environmental impact if:

- It does not meet wastewater treatment requirements of the applicable Regional Water Quality Control Board.
- The project includes features or elements that contribute to the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- The project includes features or elements that contribute to the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- As a result of the project water supplies are not available to serve the project from existing entitlements and resources, new or expanded entitlements are needed.
- Project development results in a determination by the wastewater treatment provider which serves or may serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments.

The project would generate approximately 131,250 gallons of wastewater per day with an average daily discharge of 0.29 cfs. The sewage to be generated by the project would be discharged at connections to the following existing sewer mains: (1) approximately 0.04 cfs to the County of Los Angeles sewer main at the northern terminus of Topanga Canyon Boulevard; and (2) approximately 0.25 cfs to the City of Los Angeles sewer main within Canoga Avenue, approximately 150 feet south of SR-118. The County sewer main connects to the City sewer south of SR-118.

Due to a 1998 expansion of the City's treatment and disposal facility, sewage generation associated with the project would not result in over capacity of existing or planned wastewater treatment facilities.

The following mitigation measures shall be implemented to further reduce potential impacts associated with wastewater:

- 4.14-1. Annexation to LVMWD Sewer Improvement District “B”
- 4.14-2. Reconstruct portions of the City of Los Angeles sewer system as shown in Figure 4.14.3 of the certified FEIR
- 4.14-3. Install low-flow toilets and showers to minimize sewage generation from the proposed homes

This project would have no adverse cumulative impacts on existing sewage treatment and disposal facilities because it meets the criteria on which the capacities of these facilities have been constructed and/or expanded. With implementation of proposed mitigation measures, the project would not have an adverse cumulative impact on the sewage collection system.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. Therefore, there has been a significant reduction in the residential density of this project, and corresponding reduction in wastewater generation.

As mentioned above, the 375 lots analyzed in the certified FEIR would result in an estimated average daily wastewater generation of approximately 131,250 gallons per day (“gpd”).⁴ The certified FEIR First Addendum would result in an estimated average daily wastewater generation of approximately 109,900 gpd.⁵ The Amended Project would result in an estimated average daily wastewater generation of approximately 97,400 gpd.⁶ When including the proposed wastewater generation of both the Amended Project and Twin Lakes, the estimated average daily wastewater generation would be approximately 154,210 gpd.⁷ The wastewater generation of the Amended Project is lower than the certified FEIR. Thus, the mitigation measures originally approved exceed those that would have been required for the certified FEIR First Addendum and the Approved Project.

According to the City of Los Angeles, the sewer system could accommodate the total flow for the Amended Project and Twin Lakes with implementation of the project design features listed below. Further detailed gauging and evaluation will be needed as part of the permit process to identify a specific sewer connection

⁴ 375 residential units X 350 gpd = 131,250 gpd. Based on an estimated daily sewage generation rate of 350 gpd per unit per the Findings of Fact Regarding the Final Environmental Impact Report for the Deerlake Ranch Vesting Tentative Tract Map Number 53138-(5), Conditional Use Permit Number 99-239-(5), and Oak Tree Permit Number 99-239(5).

⁵ 314 residential units X 350 gpd = 109,900 gpd. Based on an estimated daily sewage generation rate of 350 gpd per unit per the Findings of Fact Regarding the Final Environmental Impact Report for the Deerlake Ranch Vesting Tentative Tract Map Number 53138-(5), Conditional Use Permit Number 99-239-(5), and Oak Tree Permit Number 99-239(5).

⁶ Per Ali Poosti, Division Manager, Wastewater Engineering Services Division, LA Sanitation, City of Los Angeles, letter correspondence, dated June 18, 2015. Please note, while the Amended Project proposes a recreation center and the same residential units as the certified FEIR First Addendum, the Amended Project would result in less wastewater generation due to updated generation factors based on average daily flow per number of bedrooms within a single family home.

⁷ Per Ali Poosti, Division Manager, Wastewater Engineering Services Division, LA Sanitation, City of Los Angeles, letter correspondence, dated June 18, 2015.

point. If the public sewer has insufficient capacity, the developer would be required to build sewer lines to a point in the sewer system with sufficient capacity. A final approval for sewer capacity and connection permit would be made at that time.⁸ Lastly, the Project Applicant received a will serve letter from the LVMWD assuring the Amended Project connection to the sewage system of the district if the proponent satisfied all terms and conditions for services as set forth in the LVWMD's Code. Prior to connection to any existing or proposed sewer, the LVWMD will require the applicant to complete a district sewer application for service and to make financial arrangements as set forth in Title 5 of the LVMWD Code, Ordinance No. 11-86-161.⁹

The sewage flow of the Amended Project and Twin Lakes will be conveyed to the Hyperion Treatment Plant. The Hyperion Treatment Plant currently has a daily flow of 362 million gallons per day ("mgd") with a 450 mgd capacity.¹⁰ The Amended Project is expected to result in an estimated average daily wastewater generation of approximately 97,400 gpd or 154,210 gpd when including Twin Lakes. This number represents an increase of less than one percent of the daily flow and daily capacity at the Hyperion Treatment Plant. Thus, the capacity of the Hyperion Treatment would be able to accommodate the wastewater generated from operation of the Amended Project and Twin Lakes.¹¹ Therefore, wastewater generated during operation of the Amended Project and Twin Lakes would result in a less than significant impact. As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would increase impact on wastewater discharge from those analyzed in the certified FEIR and the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR with the addition of the following project design features.

The following project design features are recommended to ensure Project connection to the City of Los Angeles Sanitation District Hyperion Treatment Plant.

- Construction of an 8-inch sewer along Canoga Avenue from Candice Place to Celtic Street;
- Additional requirements such as installation of gauging equipment shall be required in order for the City of Los Angeles to bill for sewer service charges; and
- Operation of the pumping infrastructure at Candice Place shall not be in the jurisdiction of the City of Los Angeles.

CERTIFIED FEIR SECTION 4.15 - UTILITIES AND SERVICE SYSTEMS - SOLID WASTE

Summary of Analysis in Certified FEIR

Solid waste management service for the project area is provided by the County Sanitation Districts of Los Angeles County. The Sanitation Districts maintain three active sanitary landfills: (1) Calabasas Landfill, (2) Scholl Canyon Landfill, and (3) Puente Hills Landfill. The Calabasas Landfill is the closest operating landfill to the project site. However, as of February 1991, a municipal ordinance restricted the use of the landfill to solid waste originating within an identified waste shed. This ordinance pertained to certain incorporated

⁸ Ali Poosti, Division Manager, Wastewater Engineering Services Division, LA Sanitation, City of Los Angeles, letter correspondence, dated June 18, 2015.

⁹ Conditional Statement of Sewer Service, prepared by Phyllis Southard, Planning & New Development Technician, LVMWD, dated May 8, 2013.

¹⁰ City of Los Angeles, LA Sanitation Environment, website: <http://san.lacity.org/wastewater/factsfigures.htm>, accessed May 2015.

¹¹ Ali Poosti, Division Manager, Wastewater Engineering Services Division, LA Sanitation, City of Los Angeles, letter correspondence, dated June 18, 2015

and unincorporated areas of Los Angeles County, including the project area. Therefore, solid waste originating from development of the project would be sent to the Puente Hills Landfill.

The California Integrated Waste Management Act of 1989 (AB 939) requires every city and county in the State to prepare a Source Reduction and Recycling Element (SRRE) to its Solid Waste Management Plan that identifies how each jurisdiction will meet the mandatory State waste diversion goals of 50 percent by the year 2000.

The term “integrated waste management” refers to the use of a variety of waste management practices to safely and effectively handle the municipal solid waste stream with the least adverse impact on human health and the environment. The Act has established waste management prioritization as follows:

- Source reduction
- Recycling
- Composting
- Energy recover
- Landfilling
- Household hazardous waste management

State CEQA Guidelines do not identify any quantitative standards for determining the significance of a new development project’s solid waste generation. However, it does identify that a project is considered to have a significant environmental impact if:

- The project area is unable to be served by a landfill with sufficient permitted capacity to accommodate the project’s solid waste disposal needs.
- Project Development does not comply with federal, state, and local statutes and regulations related to solid waste.

Based on criteria established by the County of Los Angeles *Environmental Document Reporting Procedures and Guidelines* for utilities/other services (other than water) are adverse when:

- The service to the project site is not presently available;
- The service facility requires considerable extension to the project site; or
- There exists an inadequate service supply

Disposal of grading and construction-related waste is anticipated to be limited and would not constitute a continuous generator of solid waste after construction activities are completed. Impacts stemming from the disposal of construction-related solid waste would be less than significant due to the limited disposal activity as well as the Sanitation Districts implementation and operation of a resource and recovery program.

Solid waste generated by the project was estimated using generation rates cited by the California Integrated Waste Management Board (CIWMB) in conjunction with the Districts. With implementation of the project, a

total of 375 single-family residential units, it is estimated that the project would generate approximately 2.30 tons per day. This represents 0.017 percent of the authorized, maximum solid waste disposal rate for Puente Hills of 13,200 tons per day. However, Puente Hills Landfill is in the process of closing and will not be available for this project.

The Districts consider a new development that generates less than one percent of the authorized tons per day disposal rate as having a less than significant impact on landfill capacity. Based on this threshold criteria, the project would have a less than significant impact on solid waste generation and landfill capacity.

Although solid waste impacts are less than significant due to adequate landfill capacity serving the project, the following mitigation measures are recommended to assist in meeting the goals of the California Integrated Waste Management Act, AB 939:

- 4.15-1. The proposed project shall incorporate storage and collection of recyclables into each project design.
- 4.15-2. Refuse collection contracts shall include collection of recyclables.
- 4.15-3. All residents shall be encouraged to recycle, at a minimum, newspaper, glass, bottles, aluminum and bimetal cans and P.E.T. bottles.
- 4.15-4. Recycling shall be included in the design of the project by reserving space appropriate for the support of recycling, such as adequate storage areas and access for recycling vehicles.
- 4.15-5. All contractors shall be urged to recycle construction and demolitions wastes to the extent feasible.
- 4.15-6. The project applicant shall provide homebuyers with the following information concerning:
 - Participation in the County of Los Angeles Household Hazardous Waste Collection Program;
 - City sponsored programs including curbside oil and filter recycling; and
 - Information on the proper disposal of hazardous materials.

Given the past capacity of the Puente Hills Landfill that could have served the project site, the incremental increase in solid waste generation is considered less than significant with the knowledge that additional landfill capacity has been approved (e.g., Sunshine Canyon Landfill) since the certification of the FEIR or is in the process of approval (e.g., Chiquita Canyon Landfill or Scholl Canyon Landfill) that may receive solid waste generated by this project. Further, implementation of the proposed mitigation measures would ensure that the amount of solid waste generated by residential households assist local efforts to reduce solid waste generation area-wide.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. Therefore, there has been a significant reduction in the residential density of this project, and corresponding reduction in the production of solid wastes.

The certified FEIR would result in an estimated average daily solid waste generation of approximately 4,745 pounds per day using the generation factor of 12.23 pounds per day per unit for 388 single-family residences. The certified FEIR First Addendum would result in an estimated average daily solid waste generation of approximately 3,840 pounds per day for 314 residential units using the same generation rates as the certified FEIR.¹² The Amended Project, inclusive of the recreation center, would result in an estimated average daily solid waste generation of approximately 4,620 pounds per day,¹³ which is less than the estimate for the certified FEIR project.

The Puente Hills Landfill is full and closed and ceased operation on October 31, 2013. As such, solid waste originating from development of the project would be sent to the Scholl Canyon Landfill or possibly Sunshine Canyon Landfill or Chiquita Canyon Sanitary Landfill. The Scholl Canyon Landfill has a maximum permitted throughput of 3,400 tons per day (“tpd”) with a remaining capacity of 9,900,000 cubic yards and an estimated closure date of April 1, 2030.¹⁴ The Sunshine Canyon Landfill has a maximum permitted throughput of 12,100 tons per day (“tpd”) with a remaining capacity of 96,800,000 cubic yards and an estimated closure date of December 31, 2037.¹⁵ The Chiquita Canyon Sanitary Landfill has a maximum permitted throughput of 6,000 tons per day (“tpd”) with a remaining capacity of 22,400,000 cubic yards and an estimated closure date of November 24, 2027.¹⁶ The Amended Project is expected to generate a maximum waste disposal of 4,620 pounds per day (2.305 tpd). This number represents an increase of less than one percent of the total remaining capacity at the Scholl Canyon Landfill and even less for Sunshine Canyon and Chiquita Canyon Landfills. Thus, the capacity of these landfills would be able to accommodate the solid waste generated from operation of the Project. Therefore, solid waste generated during operation of the Project would result in a less than significant impact.

While the Amended Project would result in lower solid waste generation than the certified FEIR, all mitigation measures identified in the FEIR would apply to this modification in spite of the conservative approach used for estimating the size of the recreation center.

As such, the proposed modifications of the Amended Project proposes no significant change in project improvements that would increase impact on solid waste service from those analyzed in the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR.

¹² Although 10 pounds per dwelling unit per day is the current generation rate used by CalRecycle Waste Characterization Residential Developments: Estimated Solid Waste Generation Rates Website: <http://www.calrecycle.ca.gov/wastechar/WasteGenRates/Residential.htm>, the above analysis used the same 12.23 pounds per dwelling unit per day generation rate used in the Certified FEIR for consistency,

¹³ 3.12 pounds per 100 square feet per day was applied for other services (which includes recreational services and health clubs), per CalRecycle Waste Characterization Residential Developments: Estimated Soil Waste Generation Rates Website: <http://www.calrecycle.ca.gov/wastechar/WasteGenRates/Residential.htm>, accessed May 2015. Recreation center square footage of 25,000 square feet/100 square feet = 250 X 3.12 pounds per day = 780 pounds per day. 3,840 pounds per day + 780 pounds per day = 4,620 pounds per day.

¹⁵ CalRecycle, Facility/Site Summary Details: Sunshine Canyon Landfill (19-AA-2000), <http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AA-2000/Detail/>, accessed May 2015.

¹⁶ CalRecycle, Facility/Site Summary Details: Chiquita Canyon Sanitary Landfill (19-AA-0052), <http://www.calrecycle.ca.gov/SWFacilities/Directory/19-AA-0052/Detail/>, accessed May 2015.

CERTIFIED FEIR SECTIONS 4.16 AND 4.17 - UTILITIES AND SERVICE SYSTEMS - ELECTRICITY AND NATURAL GAS

Summary of Analysis in Certified FEIR

The project site receives electrical service from Southern California Edison (SCE). Several existing overhead electrical facilities are located throughout the property. SCE currently maintains an existing overhead 16 Kilovolt (KV) primary power line that feeds into the project site. This line feeds into an existing pole top substation that serves an existing residential subdivision to the south with a 4KV primary voltage. The 16KV line also feeds various areas throughout the proposed subdivision.

Southern California Gas Company (The Gas Company) is the principal distributor of natural gas in Southern California. The Gas Company supplies natural gas to the project vicinity through a system of subsurface gas mains and pipelines. Existing natural gas lines in the vicinity of the project site include a six-inch medium pressure main located in Topanga Canyon Boulevard. The project site is currently vacant and there is no consumption of natural gas. There are no natural gas facilities located on the project site at this time.

State CEQA Guidelines Appendix G identifies criteria for determining whether a project's energy impacts are considered to have a significant effect on the environment. Implementation of the project would result in a significant impact upon energy resources, if project development includes features or elements that:

- Encourage activities which result in the use of large amounts of fuel, water, or energy:
- Use fuel, water, or energy in a wasteful manner.

Based on criteria established by the County, project impacts regarding energy consumption would be considered significant if electricity and/or natural gas required through implementation and operation of the project would exceed the facilities and/or supply which could be accommodated and/or furnished by existing or planned SCE and/or the Gas Company facilities.

As determined by SCE, the existing overhead 16 Kilovolt (KV) primary power line that feeds into the site has adequate capacity to serve the capacity ever occur, the utility will apportion its available supply of electricity among its customers as set forth in Rule No. 14, *Shortage of Supply and Interruption of Delivery*. Further, the project would be required to comply with the energy conservation standards set forth in Title 24, Part 6, Article 2 of the California Administrative Code, which would reduce the project's demand upon electricity resources.

SCE has indicated that several of the existing overhead facilities on the property would be replaced with a new underground system. It is not anticipated that development of the project would significantly impact the supply of electricity or exceed the planned capacity of existing electricity distribution systems. Therefore, no significant impact would occur.

Although no natural gas facilities are located on the project site at this time, The Gas Company has indicated that sufficient natural gas facilities exist in the project vicinity and gas service to the project site could be provided in accordance with the California Public Utilities Commission (CPUC) without any significant impacts. Recoverable reserves and resources of natural gas total more than a 70-year supply. Further, the

project would be required to comply with State Energy Conservation Standards as stipulated in Title 24 of the California Administrative Code, which would further reduce impacts upon natural gas distribution facilities and supplies.

The Gas Company has designed the distribution pipeline system to meet the demand of total buildout in the project area. Gas facilities would be extended into the project property at the time of development.

Although energy consumption impacts are less than significant, the following mitigation measures are recommended to: (1) further reduce energy consumption impacts that may occur as a result of project implementation; and (2) assist in meeting the goals of the energy conservation standards set forth in Title 24, Part 6, Article 2 of the California Administrative Code which would reduce the project's demand upon electricity and natural gas resources.

- 4.16-1. Project built-in appliances, refrigerators, and space-conditioning equipment shall exceed the minimum efficiency levels mandated in the California Code of Regulations.
- 4.16-2. To reduce electricity consumption, fluorescent and high-intensity-discharge (HID) lamps shall be installed wherever possible, which give the highest light output per watt of electricity consumed, including all street lights consistent with the Los Angeles County of Public Works standards.
- 4.17-1. Project buildings shall be designed and constructed to be well-sealed to prevent outside air from infiltrating and increasing interior space-conditioning loads.
- 4.17-2. Thermal insulation, which exceeds requirements established by the California Code of Regulations, shall be installed in walls and ceilings.
- 4.17-3. Window systems shall be designed to reduce thermal loss, thus reducing heating loads during cool weather.
- 4.17-4. Project energy engineers and architects shall consult with The Gas Company for an energy analysis of the proposed dwellings regarding efficiency/conservation measures and up-to-date technology, manufacturing equipment, etc.

Although the project is not expected to result in significant impacts upon available energy supplies or distribution facilities, implementation of the recommended mitigation measures would further reduce project demands upon such resources. Energy consumption associated with the project would be considered less than significant.

Analysis of the Amended Project.

Since certification of the FEIR, the FEIR First Addendum was certified with a reduction in the number of residential units from 375 to 314. Similar to the certified FEIR First Addendum, the Amended Project proposes 314 residential units. Therefore, there has been a significant reduction in the residential density of this project, and corresponding reduction in the demand for electricity and natural gas.

The proposed recreation center is anticipated to have an average demand of electricity and natural gas that is equal to, or less than, one typical house proposed for this project. Therefore, with the addition of the recreation center, the Amended Project would result in an incremental increase in daily energy consumption from the certified FEIR First Addendum but less than the certified FEIR approved Project.

All mitigation measures identified in the certified FEIR will apply to this modification.

As such, the proposed modifications of the Amended Project propose no significant change in project improvements that would substantially increase impact on electricity and natural gas consumption from those analyzed in the certified FEIR First Addendum, with the same mitigation measures to be implemented as stated in the certified FEIR.

4. CONCLUSION

4.0 CONCLUSION

Based on the information given in this Second Addendum, the following findings can be made in accordance with *State CEQA Guidelines* Section 15164(a), which authorizes a Lead Agency to prepare an Addendum to a previously certified Environmental Impact Report if changes or additions to the document are necessary, but none of the conditions described in Section 15162(a) are present, as described below:

- No substantial changes are proposed in the project which will require major revisions of the previous EIR due to the involvement of new significant environmental effects or a substantial increase in the severity of previously identified significant effects
- No substantial changes have occurred with respect to the circumstances under which the project is undertaken which will require major revisions of the previous EIR due to the involvement of new potentially significant environmental effects or a substantial increase the severity of previously identified potentially significant effects
- No new information of substantial importance, which was not known, and could not have been known with the exercise of reasonable diligence at the time the previous EIR was certified as complete, shows any of the following:
 - The project will not have one or more significant effects not discussed in the previous EIR
 - Potentially significant effects previously examined will not be substantially more severe than shown in the previous EIR
 - No new mitigation measures or alternatives previously found to be infeasible have been found to be feasible but declined by the project proponent to be adopted
 - No new mitigation measures or alternatives which are considerably different from those analyzed in the previous EIR, and that would substantially reduce one or more potentially significant effects on the environment, have been found and declined by the project proponent to be adopted

Based on the analysis presented herein, it has been determined that the Amended Project would not result in any new significant impacts or a substantial increase in the severity of an impact disclosed in the certified FEIR or otherwise require preparation of a subsequent or supplemental EIR. Therefore, preparation of this Second Addendum to the certified FEIR under CEQA is the appropriate document in support of the County's consideration of the Amended Project. The environmental analysis relies in part on the analyses completed in the previous certified FEIR and certified FEIR First Addendum, and directly references the EIR, where appropriate. This Second Addendum has appropriately disclosed the potential impacts from the Amended Project and will be included as part of the CEQA record for the Amended Project.
